

1 Conditional Expectation

Definition. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space. Let $(X_i)_{i \in I}$ be a collection of random variables defined on this space. Then we define $\sigma(X_i : i \in I) \subseteq \mathcal{F}$ to be the smallest σ -algebra such that all of the X_i are measurable, i.e

$$\sigma(X_i : i \in I) = \sigma(X_i^{-1}(B) : i \in I, B \in \mathcal{B}(\mathbb{R})).$$

Definition. If $B \in \mathcal{F}$ has $\mathbb{P}(B) > 0$ then we define

$$\mathbb{P}(A|B) = \frac{\mathbb{P}(A \cap B)}{\mathbb{P}(B)}$$

for any $A \in \mathcal{F}$. Furthermore, if X is an integrable random variable we define

$$\mathbb{E}[X|B] = \frac{\mathbb{E}[X \mathbb{1}(B)]}{\mathbb{P}(B)}.$$

Definition. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space. We say a σ -algebra \mathcal{G} is countably generated if there exist $(B_i)_{i \in I}$ pairwise disjoint (with I countable) such that $\bigcup_{i \in I} B_i = \Omega$ and $\mathcal{G} = \sigma(B_i : i \in I)$.

Let X be an integrable random variable and \mathcal{G} a countably generated σ -algebra. We want to define $X' = \mathbb{E}[X|\mathcal{G}]$. So define

$$X'(\omega) = \mathbb{E}[X|B_i] \text{ whenever } \omega \in B_i.$$

Or equivalently,

$$X'(\omega) = \sum_{i \in I} \mathbb{E}[X|B_i] \mathbb{1}(\omega \in B_i)$$

where we use the convention that $\mathbb{E}[X|B_i] = 0$ if $\mathbb{P}(B_i) = 0$. Then X' is indeed \mathcal{G} -measurable (note \mathcal{G} is the set of $\bigcup_{j \in J} B_j$ for $J \subseteq I$).

Note that for any $G \in \mathcal{G}$ we have $\mathbb{E}[X \mathbb{1}(G)] = \mathbb{E}[X' \mathbb{1}(G)]$. Also

$$\mathbb{E}[|X'|] \leq \mathbb{E} \left[\sum_{i \in I} \mathbb{E}[|X||B_i] \mathbb{1}(B_i) \right] = \sum_{i \in I} \mathbb{E}[|X||B_i] \mathbb{P}(B_i) = \mathbb{E}[|X|] < \infty$$

so X' is integrable.

Theorem (Monotone convergence theorem). *Let $(X_n)_{n \geq 1}$ be a sequence of non-negative random variables with $X_n \uparrow X$ as $n \rightarrow \infty$ almost-surely. Then $\mathbb{E}X_n \uparrow \mathbb{E}X$ as $n \rightarrow \infty$.*

Proof. See Part II Probability & Measure. □

Theorem (Dominated convergence theorem). *Let $(X_n)_{n \geq 1}$ be a sequence of random variables with $X_n \rightarrow X$ as $n \rightarrow \infty$ almost-surely and $|X_n| \leq Y$ almost-surely for some Y integrable. Then $\mathbb{E}X_n \rightarrow \mathbb{E}X$ as $n \rightarrow \infty$.*

Proof. See Part II Probability & Measure. □

Definition (L^p). Let $p \in [1, \infty]$ and f be a measurable function. Define the L^p -norm

$$\|f\|_p = (\mathbb{E}[|f|^p])^{1/p} \text{ for } p \in [1, \infty)$$

$$\|f\|_\infty = \inf\{\lambda : |f| \leq \lambda \text{ a.e.}\}.$$

Furthermore write $f \sim g$ if $f = g$ almost-everywhere. Then define the L^p -space $\mathcal{L}^p(\Omega, \mathcal{F}, \mathbb{P}) = \{f : \|f\|_p < \infty\} / \sim$.

Theorem (\mathcal{L}^2 is a Hilbert space). *$\mathcal{L}^2(\Omega, \mathcal{F}, \mathbb{P})$ is a Hilbert space with inner product $\langle U, V \rangle = \mathbb{E}[UV]$. For a closed subspace \mathcal{H} , if $f \in \mathcal{L}^2$ there exists a unique $g \in \mathcal{H}$ with $\|f - g\|_2 = \inf\{\|f - h\|_2 : h \in \mathcal{H}\}$ and $\langle f - g, h \rangle = 0$ for all $h \in \mathcal{H}$. g is called the orthogonal projection of f on \mathcal{H} .*

Proof. See Part II Probability & Measure. □

Theorem (Conditional expectation). *Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space and $\mathcal{G} \subseteq \mathcal{F}$ a sub σ -algebra, $X \in \mathcal{L}^1(\Omega, \mathcal{F}, \mathbb{P})$. Then there exists an integrable random variable Y satisfying*

- (a) Y is \mathcal{G} -measurable;
- (b) for all $A \in \mathcal{G}$, $\mathbb{E}[X \mathbb{1}(A)] = \mathbb{E}[Y \mathbb{1}(A)]$.

Moreover Y is unique, in the sense that if Y' also satisfies (a) and (b), then $Y = Y'$ almost-surely. We call Y a version of the conditional expectation of X given \mathcal{G} . We write $Y = \mathbb{E}[X|\mathcal{G}]$ almost-surely. If $\mathcal{G} = \sigma(Z)$ for a random variable Z , then we write $\mathbb{E}[X|Z] = \mathbb{E}[X|\mathcal{G}]$.

Remark. (b) could be replaced by $\mathbb{E}[XZ] = \mathbb{E}[YZ]$ for all Z bounded and \mathcal{G} -measurable.

Proof. First we show uniqueness. Suppose Y and Y' both satisfy (a) and (b) and let $A = \{Y > Y'\} \in \mathcal{G}$. Then

$$\mathbb{E}[Y \mathbb{1}(A)] = \mathbb{E}[Y' \mathbb{1}(A)] \Rightarrow \mathbb{E}[(Y - Y') \mathbb{1}(A)] = 0 \Rightarrow \mathbb{P}(Y > Y') = 0 \Rightarrow Y \leq Y' \text{ a.s.}$$

and similarly $Y \geq Y'$ a.s.

Now we show existence. First assume $X \in \mathcal{L}^2(\Omega, \mathcal{F}, \mathbb{P})$. Then $\mathcal{L}^2(\Omega, \mathcal{G}, \mathbb{P})$ is a closed subspace of $\mathcal{L}^2(\mathcal{F})$. Hence

$$\mathcal{L}^2(\mathcal{F}) = \mathcal{L}^2(\mathcal{G}) \oplus \mathcal{L}^2(\mathcal{G})^\perp$$

so we can write $X = Y + Z$ for $Y \in \mathcal{L}^2(\mathcal{G})$ and $Z \in \mathcal{L}^2(\mathcal{G})^\perp$. Define $\mathbb{E}[X|\mathcal{G}] = Y$, so Y is \mathcal{G} -measurable and for all $A \in \mathcal{G}$

$$\mathbb{E}[X \mathbb{1}(A)] = \mathbb{E}[Y \mathbb{1}(A)] + \underbrace{\mathbb{E}[Z \mathbb{1}(A)]}_{=0} = \mathbb{E}[Y \mathbb{1}(A)].$$

We claim that if $X \geq 0$ almost-surely, then $Y \geq 0$ almost-surely. Indeed, let $A = \{Y < 0\} \in \mathcal{G}$ so $0 \leq \mathbb{E}[X \mathbb{1}(Y < 0)] = \mathbb{E}[Y \mathbb{1}(Y < 0)] \leq 0$ which implies $\mathbb{P}(Y < 0) = 0$.

Assume now that $X \geq 0$ almost-surely. Define $X_n = X \wedge n \leq n$, so $X_n \in \mathcal{L}^2$ for all n . Let $Y_n = \mathbb{E}[X_n|\mathcal{G}]$. Then X_n is an increasing sequence and by the above claim, Y_n is also an increasing sequence almost-surely. Define $Y = \limsup_{n \rightarrow \infty} Y_n$, so Y is \mathcal{G} -measurable. Also $Y = \uparrow \lim_{n \rightarrow \infty} Y_n$ almost-surely. For any $A \in \mathcal{G}$ we have

$$\mathbb{E}[X \mathbb{1}(A)] = \lim_{n \rightarrow \infty} \mathbb{E}[X_n \mathbb{1}(A)] = \lim_{n \rightarrow \infty} \mathbb{E}[Y_n \mathbb{1}(A)] = \mathbb{E}[Y \mathbb{1}(A)]$$

by the Monotone Convergence Theorem.

Finally, for general X write $X = X^+ - X^-$ and define $\mathbb{E}[X|\mathcal{G}] = \mathbb{E}[X^+|\mathcal{G}] - \mathbb{E}[X^-|\mathcal{G}]$. \square

Remark. From the last proof we can see that we can define $\mathbb{E}[X|\mathcal{G}]$ for $X \geq 0$ without assuming integrability of X . It satisfies all the conditions apart from integrability.

Definition. Let $(\mathcal{G}_n)_{n \geq 1}$ be sub σ -algebras of \mathcal{F} . We call them *independent* if whenever $G_i \in \mathcal{G}_i$ and $i_1 < i_2 < \dots < i_k$ we have

$$\mathbb{P}(G_{i_1} \cap \dots \cap G_{i_k}) = \prod_{j=1}^k \mathbb{P}(G_{i_j}).$$

For a random variable X and a σ -algebra \mathcal{G} , we say they are *independent* if $\sigma(X)$ is independent of \mathcal{G} .

Properties of conditional expectation

Let $X, Y \in \mathcal{L}^1$, $\mathcal{G} \subseteq \mathcal{F}$ a sub σ -algebra. Then

1. $\mathbb{E}[\mathbb{E}[X|\mathcal{G}]] = \mathbb{E}[X]$ (take $A = \Omega$);
2. If X is \mathcal{G} -measurable then $\mathbb{E}[X|\mathcal{G}] = X$ almost-surely (X clearly satisfies the conditions);
3. If X is independent of \mathcal{G} , then $\mathbb{E}[X|\mathcal{G}] = \mathbb{E}[X]$ almost-surely;
4. If $X \geq 0$ almost-surely then $\mathbb{E}[X|\mathcal{G}] \geq 0$ almost-surely;
5. For $\alpha, \beta \in \mathbb{R}$, $\mathbb{E}[\alpha X + \beta Y|\mathcal{G}] = \alpha \mathbb{E}[X|\mathcal{G}] + \beta \mathbb{E}[Y|\mathcal{G}]$ almost-surely;
6. $|\mathbb{E}[X|\mathcal{G}]| \leq \mathbb{E}[|X||\mathcal{G}]$ almost-surely.

Recall:

Theorem (Fatou's Lemma). *If $X_n \geq 0$ for all n almost-surely, then*

$$\mathbb{E}[\liminf_{n \geq 1} X_n] \leq \liminf_{n \geq 1} \mathbb{E}X_n.$$

Proof. See Part II Probability & Measure. □

Theorem (Jensen's Inequality). *If X is integrable, $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ is convex, then*

$$\mathbb{E}[\varphi(X)] \geq \varphi(\mathbb{E}[X]).$$

We consider any analogues of our convergence theorems for conditional expectation.

Theorem (Conditional Monotone Convergence Theorem). *Suppose $X_n \geq 0$ for all n and $X_n \uparrow X$ almost-surely as $n \rightarrow \infty$. Let \mathcal{G} be a sub σ -algebra of \mathcal{F} . Then $\mathbb{E}[X_n|\mathcal{G}] \uparrow \mathbb{E}[X|\mathcal{G}]$ almost-surely.*

Remark. Note that $\mathbb{E}[X_n|\mathcal{G}] \uparrow \mathbb{E}[X|\mathcal{G}]$ in the almost-sure sense, as these are random variables.

Proof. Let $Y_n = \mathbb{E}[X_n|\mathcal{G}]$ almost-surely. Then Y_n is increasing. Set $Y = \limsup_{n \geq 1} Y_n$. Since Y_n is \mathcal{G} -measurable, Y is \mathcal{G} -measurable. Also $Y = \uparrow \lim_{n \geq 1} Y_n$ almost-surely. We need to show $\mathbb{E}[Y\mathbb{1}(A)] = \mathbb{E}[X\mathbb{1}(A)]$ for all $A \in \mathcal{G}$. This follows from the usual Monotone Convergence Theorem as

$$\mathbb{E}[Y\mathbb{1}(A)] = \lim_{n \geq 1} \mathbb{E}[Y_n\mathbb{1}(A)] = \lim_{n \geq 1} \mathbb{E}[X_n\mathbb{1}(A)] = \mathbb{E}[X\mathbb{1}(A)].$$

□

Theorem (Conditional Fatou's Lemma). *Let $(X_n)_{n \geq 1}$ be a non-negative sequence of random variables. Then*

$$\mathbb{E}[\liminf_{n \rightarrow \infty} X_n|\mathcal{G}] \leq \liminf_{n \rightarrow \infty} \mathbb{E}[X_n|\mathcal{G}] \text{ almost-surely.}$$

Proof. Note that $\inf_{k \geq n} X_k \uparrow \liminf_{n \rightarrow \infty} X_n$ so by the conditional MCT

$$\lim_{n \rightarrow \infty} \mathbb{E}[\inf_{k \geq n} X_k|\mathcal{G}] = \mathbb{E}[\liminf_{n \rightarrow \infty} X_n|\mathcal{G}].$$

We also have

$$\mathbb{E}[\inf_{k \geq n} X_k|\mathcal{G}] \leq \mathbb{E}[X_k|\mathcal{G}] \quad \forall k \geq n \text{ almost-surely.}$$

Which implies

$$\mathbb{E}[\inf_{k \geq n} X_k|\mathcal{G}] \leq \inf_{k \geq n} \mathbb{E}[X_k|\mathcal{G}] \quad \forall k \geq n \text{ almost-surely}$$

since k takes countable values (intersection of countable sets of full measure also has full measure). Now taking limits as $n \rightarrow \infty$ we are done. □

Theorem (Conditional Dominated Convergence Theorem). *Suppose $X_n \rightarrow X$ almost-surely, $|X_n| \leq Y$ almost-surely with Y integrable. Then $\mathbb{E}[X_n|\mathcal{G}] \rightarrow \mathbb{E}[X|\mathcal{G}]$ almost-surely.*

Proof. We apply the Conditional Fatou's Lemma. Indeed $-Y \leq X_n \leq Y$ so $X_n + Y \geq 0$ and $Y - X_n \geq 0$ for all n . By Conditional Fatou's Lemma

$$\mathbb{E}[X|\mathcal{G}] + \mathbb{E}[Y|\mathcal{G}] = \mathbb{E}[X + Y|\mathcal{G}] = \mathbb{E}[\liminf_{n \rightarrow \infty} (X_n + Y)] \leq \liminf_{n \rightarrow \infty} \mathbb{E}[X_n|\mathcal{G}] + \mathbb{E}[Y|\mathcal{G}]$$

and

$$\mathbb{E}[Y|\mathcal{G}] - \mathbb{E}[X|\mathcal{G}] = \mathbb{E}[\liminf_{n \rightarrow \infty} (Y - X_n)|\mathcal{G}] \leq \mathbb{E}[Y|\mathcal{G}] + \liminf_{n \rightarrow \infty} (-\mathbb{E}[X_n|\mathcal{G}]).$$

Hence $\limsup_{n \rightarrow \infty} \mathbb{E}[X_n|\mathcal{G}] \leq \mathbb{E}[X|\mathcal{G}]$ and $\liminf_{n \rightarrow \infty} \mathbb{E}[X_n|\mathcal{G}] \geq \mathbb{E}[X|\mathcal{G}]$ almost-surely. □

Theorem (Conditional Jensen's Inequality). *Let X be integrable, $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ a convex function such that $\varphi(X)$ is integrable or $\varphi(X) \geq 0$. Then $\mathbb{E}[\varphi(X)|\mathcal{G}] \geq \varphi(\mathbb{E}[X|\mathcal{G}])$ almost-surely.*

Proof. We claim that $\varphi(x) = \sup_{i \in \mathbb{N}}(a_i x + b_i)$, $a_i, b_i \in \mathbb{R}$.

Then $\varphi(X) = \sup_{i \in \mathbb{N}}(a_i X + b_i)$. So

$$\mathbb{E}[\varphi(X)|\mathcal{G}] \geq \sup_{n \geq 1} (a_n \mathbb{E}[X|\mathcal{G}] + b_n) \quad \forall i \in \mathbb{N} \text{ almost-surely.}$$

□

Note. We need the supremum in the claim to be over a countable set so we can preserve the almost-sure property of an inequality.

Corollary. For all $p \in [1, \infty)$ we have

$$\|\mathbb{E}[X|\mathcal{G}]\|_p \leq \|X\|_p.$$

Proof. Apply conditional Jensen ($x \mapsto x^p$ is convex). □

Theorem (Tower property). Let X be integrable and $\mathcal{H} \subseteq \mathcal{G} \subseteq \mathcal{F}$ sub σ -algebras. Then

$$\mathbb{E}[\mathbb{E}[X|\mathcal{G}]|\mathcal{H}] = \mathbb{E}[X|\mathcal{H}] \text{ almost-surely.}$$

Proof. $\mathbb{E}[X|\mathcal{H}]$ is certainly \mathcal{H} -measurable so it remains to check

$$\mathbb{E}[\mathbb{E}[X|\mathcal{G}]\mathbb{1}(A)] = \mathbb{E}[\mathbb{E}[X|\mathcal{H}]\mathbb{1}(A)] \quad \forall A \in \mathcal{H}.$$

But since $A \in \mathcal{G}$ whenever $A \in \mathcal{H}$ we have

$$\mathbb{E}[\mathbb{E}[X|\mathcal{G}]\mathbb{1}(A)] = \mathbb{E}[X\mathbb{1}(A)] = \mathbb{E}[\mathbb{E}[X|\mathcal{H}]\mathbb{1}(A)].$$

□

Proposition. Let $X \in \mathcal{L}^1$, $\mathcal{G} \subseteq \mathcal{F}$ a sub σ -algebra, Y bounded and \mathcal{G} -measurable. Then

$$\mathbb{E}[XY|\mathcal{G}] = Y\mathbb{E}[X|\mathcal{G}] \text{ almost-surely.}$$

Proof. $Y\mathbb{E}[X|\mathcal{G}]$ is certainly \mathcal{G} -measurable. Also for any $A \in \mathcal{G}$

$$\mathbb{E}[XY\mathbb{1}(A)] = \mathbb{E}[X \underbrace{(Y\mathbb{1}(A))}_{\substack{\text{bounded,} \\ \mathcal{G}\text{-measurable}}}] = \mathbb{E}[\mathbb{E}[X|\mathcal{G}](Y\mathbb{1}(A))].$$

□

Definition. Let \mathcal{A} be a collection of sets. It is called a π -system if whenever $A, B \in \mathcal{A}$ we have $A \cap B \in \mathcal{A}$.

Recall

Theorem (Uniqueness of extension). *Let (E, \mathcal{E}) be a measurable space and let \mathcal{A} be a π -system generating \mathcal{E} . Let μ, ν be two measures on (E, \mathcal{E}) with $\mu(E) = \nu(E) < \infty$. If $\mu = \nu$ on \mathcal{A} , then $\mu = \nu$ on \mathcal{E} .*

Proof. See Part II Probability & Measure. \square

Theorem. Let $X \in \mathcal{L}^1$, $\mathcal{G}, \mathcal{H} \subseteq \mathcal{F}$ sub σ -algebras. Assume $\sigma(X, \mathcal{G})$ is independent of \mathcal{H} . Then

$$\mathbb{E}[X|\sigma(\mathcal{G}, \mathcal{H})] = \mathbb{E}[X|\mathcal{G}] \text{ almost-surely.}$$

Proof. We need to show $\mathbb{E}[X\mathbb{1}(F)] = \mathbb{E}[\mathbb{E}[X|\mathcal{G}]\mathbb{1}(F)]$ for all $F \in \sigma(\mathcal{G}, \mathcal{H})$. Define $\mathcal{A} = \{A \cap B : A \in \mathcal{G}, B \in \mathcal{H}\}$. This is a π -system generating $\sigma(\mathcal{G}, \mathcal{H})$. If $F = A \cap B$, $A \in \mathcal{G}, B \in \mathcal{H}$ then

$$\begin{aligned} \mathbb{E}[X\mathbb{1}(A \cap B)] &= \mathbb{E}\left[\underbrace{(X\mathbb{1}(A))}_{\sigma(X, \mathcal{G})\text{measurable}} \mathbb{1}(B)\right] \\ &= \mathbb{E}[X\mathbb{1}(A)]\mathbb{P}(B) \\ &= \mathbb{E}\left[\underbrace{\mathbb{E}[X|\mathcal{G}]\mathbb{1}(A)}_{\mathcal{G}\text{measurable}}\right]\mathbb{P}(B) \\ &= \mathbb{E}[\mathbb{E}[X|\mathcal{G}]\mathbb{1}(A)\mathbb{1}(B)]. \end{aligned}$$

Assume $X \geq 0$. Define $\mu(F) = \mathbb{E}[X\mathbb{1}(F)]$ and $\nu(F) = \mathbb{E}[\mathbb{E}[X|\mathcal{G}]\mathbb{1}(F)]$ for $F \in \sigma(\mathcal{G}, \mathcal{H})$. Then $\mu = \nu$ on \mathcal{A} by the above and $\mu(\Omega) = \nu(\Omega) < \infty$. Therefore $\mu = \nu$ on $\sigma(\mathcal{G}, \mathcal{H})$. \square

Definition. We say $(X_1, \dots, X_n) \in \mathbb{R}^n$ has the *Gaussian distribution* iff for all $a_1, \dots, a_n \in \mathbb{R}$

$$a_1X_1 + \dots + a_nX_n$$

has the Gaussian distribution in \mathbb{R} .

A process $(X_t)_{t \geq 0}$ is called a *Gaussian process* if $\forall t_1 < t_2 < \dots < t_n$, the vector $(X_{t_1}, \dots, X_{t_n})$ is a Gaussian random vector.

Example. Let (X, Y) be a Gaussian vector in \mathbb{R}^2 . We want to compute $\mathbb{E}[X|Y] = \mathbb{E}[X|\sigma(Y)]$. Let $X' = \mathbb{E}[X|Y]$. Since X' is $\sigma(Y)$ -measurable it follows X' is a measurable function of Y . So are looking for f Borel such that $\mathbb{E}[X|Y] = f(Y)$ almost-surely. Let $f(y) = ay + b$ for some $a, b \in \mathbb{R}$ to be determined.

Since $\mathbb{E}[X'] = \mathbb{E}[X]$ we have $a\mathbb{E}Y + b = \mathbb{E}X$. Also

$$\begin{aligned}\mathbb{E}[XY] &= \mathbb{E}[X'Y] \implies \mathbb{E}[(X - X')Y] = 0 \\ &\implies \text{Cov}(X - X', Y) = 0 \\ &\implies \text{Cov}(X, Y) = a\text{Var}(Y)\end{aligned}$$

so we have determined a, b . We need to check that for any Z bounded and $\sigma(Y)$ -measurable we have $\mathbb{E}[(X - X')Z] = 0$. Write $Z = g(Y)$ and note $\text{Cov}(X - X', Y) = 0$, implying $X - X'$ is independent of Y . Therefore $\mathbb{E}[(X - X')g(Y)] = \mathbb{E}[X - X']\mathbb{E}[g(Y)] = 0$.

Example. Let (X, Y) be a random vector in \mathbb{R}^2 with joint density function $f_{X,Y}(x, y)$. Let $h : \mathbb{R} \rightarrow \mathbb{R}$ be a Borel function such that $h(X)$ is integrable. We want to compute $\mathbb{E}[h(X)|Y]$. Note

$$\mathbb{E}[h(X)g(Y)] = \int_{\mathbb{R}^2} h(x)g(y)f_{X,Y}(x, y)dx dy$$

and write

$$f_Y(y) = \int_{\mathbb{R}} f_{X,Y}(x, y)dx$$

for the density of Y . So (using the convention $0/0 = 0$)

$$\int_{\mathbb{R}} \left(\int_{\mathbb{R}} h(x) \frac{f_{X,Y}(x, y)}{f_Y(y)} dx \right) g(y) f_Y(y) dy$$

define

$$\varphi(y) = \begin{cases} \int_{\mathbb{R}} h(x) \frac{f_{X,Y}(x, y)}{f_Y(y)} dx & \text{if } f_Y(y) > 0 \\ 0 & \text{otherwise} \end{cases}.$$

Then $\mathbb{E}[h(X)|Y] = \varphi(Y)$ almost-surely.

2 Martingales

2.1 Discrete-time Martingales

Definition. Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space. A *filtration* is a sequence of increasing sub σ -algebras of \mathcal{F} , $(\mathcal{F}_n)_{n \geq 0}$, $\mathcal{F}_n \subseteq \mathcal{F}_{n+1}$. We call $(\Omega, \mathcal{F}, (\mathcal{F}_n)_{n \geq 0}, \mathbb{P})$ a *filtered probability space*.

If $X = (X_n)_{n \geq 0}$ is a sequence of random variables on $(\Omega, \mathcal{F}, \mathbb{P})$, define $\mathcal{F}_n^X = \sigma(X_k : k \leq n)$, the *natural filtration* associated with X . We say X is *adapted* to a filtration (\mathcal{F}_n) if X_n is \mathcal{F}_n -measurable for all n . X is *integrable* if X_n is integrable for all n .

Definition. Let $(\Omega, \mathcal{F}, (\mathcal{F}_n)_{n \geq 0}, \mathbb{P})$ be a filtered probability space. We say an integrable adapted process $X = (X_n)_{n \geq 0}$ is called a

- *martingale* if

$$\mathbb{E}[X_n|\mathcal{F}_m] = X_m \text{ almost-surely } \forall n \geq m.$$

- *super-martingale* if

$$\mathbb{E}[X_n|\mathcal{F}_m] \leq X_m \text{ almost-surely } \forall n \geq m.$$

- *sub-martingale* if

$$\mathbb{E}[X_n|\mathcal{F}_m] \geq X_m \text{ almost-surely } \forall n \geq m.$$

Remark. If X is a martingale with respect to (\mathcal{F}_n) , then it is also a martingale with respect to the natural filtration (\mathcal{F}_n^X) .

Example. Let (ξ_i) be a sequence of iid random variables with $\mathbb{E}[\xi_1] = 0$. Let $X_n = \xi_1 + \dots + \xi_n$, $X_0 = 0$. This is a martingale. We have

$$\mathbb{E}[X_n|\mathcal{F}_{n-1}] = \xi_1 + \dots + \xi_{n-1} + \mathbb{E}[\xi_n|\mathcal{F}_{n-1}] = \xi_1 + \dots + \xi_{n-1}$$

by independence.

Example. Let (ξ_i) be a sequence of iid random variables with $\mathbb{E}[\xi_1] = 1$. Let $X_n = \prod_{i=1}^n \xi_i$, $X_0 = 1$. This is a martingale.

Definition. Let $(\Omega, \mathcal{F}, (\mathcal{F}_n)_{n \geq 0}, \mathbb{P})$ be a filtered probability space. A *stopping time* T is a random variable $T : \Omega \rightarrow \mathbb{Z}_+ \cup \{\infty\}$ such that $\{T \leq n\} \in \mathcal{F}_n$ for all n .

Note. T being a stopping time is equivalent to $\{T = n\} \in \mathcal{F}_n$ for all n .

Examples.

- Constant times are trivial stopping times;
- Suppose $(X_n)_{n \geq 0}$ is an adapted process taking values in \mathbb{R} . For $A \in \mathcal{B}$ define $T_A = \inf\{n \geq 0 : X_n \in A\}$ (with the convention that $\inf \emptyset = \infty$). Then $\{T_A \leq n\} = \bigcup_{k \leq n} \{X_k \in A\} \in \mathcal{F}_n$, so T_A is a stopping time;
- In the setting above, let $L_A = \sup\{n \geq 0 : X_n \in A\}$. This is in general not a stopping time.

Proposition. Let $S, T, (T_n)$ be stopping times. Then $S \wedge T$, $S \vee T$, $\inf T_n$, $\sup T_n$, $\liminf T_n$ and $\limsup T_n$ are also stopping times.

Proof. Follows directly from the definition. \square

Definition. If T is a stopping time, we define

$$\mathcal{F}_T = \{A \in \mathcal{F} : A \cap \{T \leq t\} \in \mathcal{F}_t, \forall t\}.$$

If $(X_n)_{n \geq 0}$ is a process, write $X_T(\omega) = X_{T(\omega)}(\omega)$ whenever $T(\omega) < \infty$. We define the *stopped process* $X_t^T = X_{T \wedge t}$.

Proposition. Let S and T be stopping times and let X be an adapted process. Then

1. If $S \leq T$, then $\mathcal{F}_S \subseteq \mathcal{F}_T$;
2. $X_T \mathbb{1}(T < \infty)$ is \mathcal{F}_T -measurable;
3. X^T is adapted;
4. If X is integrable, then X^T is also integrable.

Proof.

1. Immediate from the definition;
2. Let $A \in \mathcal{B}(\mathbb{R})$. We need to show $\{X_T \mathbb{1}(T < \infty) \in A\} \in \mathcal{F}_T$. Note that

$$\{X_T \mathbb{1}(T < \infty) \in A\} \cap \{T \leq t\} = \bigcup_{s=0}^t \underbrace{\{X_s \in A\}}_{\in \mathcal{F}_s \subseteq \mathcal{F}_t} \cap \underbrace{\{T = s\}}_{\in \mathcal{F}_s} \in \mathcal{F}_t.$$

3. $X_t^T = X_{T \wedge t}$ is $\mathcal{F}_{T \wedge t}$ -measurable so \mathcal{F}_t -measurable by (1).

4. We have

$$\begin{aligned}\mathbb{E}[|X_t^T|] &= \mathbb{E}[|X_{T \wedge t}|] = \sum_{s=0}^{t-1} \mathbb{E}[|X_s| \mathbb{1}(T = s)] + \mathbb{E}[|X_t| \mathbb{1}(T \geq t)] \\ &\leq \sum_{s=0}^t \mathbb{E}[|X_s|] < \infty.\end{aligned}$$

□

Theorem (Optional Stopping Theorem). *Let (X_n) be a martingale.*

1. *If T is a stopping time, then X^T is also a martingale. In particular $\mathbb{E}[X_{T \wedge t}] = \mathbb{E}[X_0]$ for all t ;*
2. *If $S \leq T$ are bounded stopping times then $\mathbb{E}[X_T | \mathcal{F}_S] = X_S$ almost-surely, and $\mathbb{E}[X_T] = \mathbb{E}[X_S]$;*
3. *If there exists an integrable random variable Y such that $|X_n| \leq Y$ for all n , and T is finite almost-surely then $\mathbb{E}[X_T] = \mathbb{E}[X_0]$;*
4. *If there exists $M > 0$ such that $|X_{n+1} - X_n| \leq M$ for all n , and T is a stopping time with $\mathbb{E}T < \infty$, then $\mathbb{E}[X_T] = \mathbb{E}[X_0]$.*

Proof.

1. We need to show that for all t we have

$$\mathbb{E}[X_{T \wedge t} | \mathcal{F}_{t-1}] = X_{T \wedge (t-1)}$$

almost-surely. Indeed

$$\begin{aligned}\mathbb{E}[X_{T \wedge t} | \mathcal{F}_{t-1}] &= \mathbb{E}\left[\sum_{s=0}^{t-1} X_s \mathbb{1}(T = s) | \mathcal{F}_{t-1}\right] + \mathbb{E}[X_t \mathbb{1}(T \geq t) | \mathcal{F}_{t-1}] \\ &= \sum_{s=0}^{t-1} X_s \mathbb{1}(T = s) + \mathbb{1}(T \geq t) X_{t-1} \\ &= X_{T \wedge (t-1)}\end{aligned}$$

using the fact that $\mathbb{1}(T \geq t)$ is \mathcal{F}_{t-1} -measurable;

2. Suppose $S \leq T \leq n$ and let $A \in \mathcal{F}_S$. We need to show $\mathbb{E}[X_T \mathbb{1}(A)] = \mathbb{E}[X_S \mathbb{1}(A)]$. Note

$$\begin{aligned}X_T - X_S &= (X_T - X_{T-1}) + \dots + (X_{S+1} - X_S) \\ &= \sum_{k \geq 0} (X_{k+1} - X_k) \mathbb{1}(S \leq k < T) \\ &= \sum_{k=0}^n (X_{k+1} - X_k) \mathbb{1}(S \leq k < T). \quad (T \leq n)\end{aligned}$$

Hence

$$\begin{aligned}\mathbb{E}[X_T \mathbb{1}(A)] &= \mathbb{E}[X_S \mathbb{1}(A)] + \sum_{k=0}^n \mathbb{E}[(X_{k+1} - X_k) \underbrace{\mathbb{1}(S \leq k < T) \mathbb{1}(A)}_{\in \mathcal{F}_k}] \\ &= \mathbb{E}[X_S \mathbb{1}(A)]\end{aligned}$$

since $\mathbb{E}[X_{k+1} | \mathcal{F}_k] = X_k$ almost-surely. Taking expectations gives $\mathbb{E}[X_T] = \mathbb{E}[X_S]$;

3. Example Sheet;
4. Example Sheet.

□

Note. Analogous results follow if (X_n) is instead a sub/super-martingale.

Corollary. If X is a positive super-martingale, T is a stopping time, $T < \infty$ almost-surely, then $\mathbb{E}[X_T] \leq \mathbb{E}[X_0]$.

Proof. Fatou's lemma gives $\mathbb{E}[\liminf_t X_{T \wedge t}] \leq \liminf_t \mathbb{E}[X_{T \wedge t}] \leq \mathbb{E}[X_0]$. □

Example. Let $(\xi_i)_{i \geq 0}$ be iid with $\mathbb{P}(\xi_0 = 1) = \mathbb{P}(\xi_0 = -1) = 1/2$. Define $X_0 = 0$ and $X_n = \sum_{i=1}^n \xi_i$ for $n \geq 1$. Then $(X_n)_{n \geq 0}$ is a martingale. Define $T = \inf\{n \geq 0 : X_n = 1\}$. Then $\mathbb{P}(T < \infty) = 1$ and for all t we have $\mathbb{E}[X_{T \wedge t}] = 0$, while $\mathbb{E}[X_T] = 1$. Hence (4) from the previous theorem tells us $\mathbb{E}T = \infty$.

Example. Consider a SRW on \mathbb{Z} , $X_0 = 0$, $X_n = \sum_{i=1}^n \xi_i$ with $(\xi_i)_{i \geq 1}$ iid taking values ± 1 with equal probability. Define $T_c = \inf\{n \geq 0 : X_n = c\}$ and set $T = T_{-a} \wedge T_b$. What is $\mathbb{P}(T_{-a} < T_b)$?

We have that $X_n^T = X_{T \wedge n}$ is a martingale by the optional stopping theorem. Furthermore $|X_{n+1} - X_n| = 1$ for all n . Need to check $\mathbb{E}[T] < \infty$: consider blocks

- ξ_1, \dots, ξ_{a+b}
- $\xi_{a+b+1}, \dots, \xi_{2(a+b)}$
- $\xi_{2(a+b)+1}, \dots, \xi_{3(a+b)}$
- \vdots

note that the probability the ξ_i in one of these blocks are all equal to either 1 or -1 is $2 \cdot 2^{-(a+b)}$. Hence $T \leq (a+b)\text{Geo}(2 \cdot 2^{-(a+b)})$ and $\mathbb{E}T \leq (a+b)2^{a+b-1} < \infty$.

So applying the optional stopping theorem to T we have $\mathbb{E}[X_T] = \mathbb{E}[X_0] = 0$. Hence $-a\mathbb{P}(T_{-a} < T_b) + b\mathbb{P}(T_b < T_{-a}) = 0$ and $\mathbb{P}(T_{-a} < T_b) + \mathbb{P}(T_b < T_{-a})$, which gives $\mathbb{P}(T_{-a} < T_b) = \frac{b}{a+b}$.

Martingale convergence theorem

Theorem (Almost-sure martingale convergence theorem). *Let X be a supermartingale bounded in \mathcal{L}^1 , i.e $\sup_{n \geq 0} \mathbb{E}|X_n| < \infty$. Then there exists a random variable $X_\infty \in \mathcal{L}^1(\mathcal{F}_\infty)$ where $\mathcal{F}_\infty = \sigma(\mathcal{F}_n : n \geq 0)$ such that $X_n \rightarrow X_\infty$ almost-surely as $n \rightarrow \infty$.*

Before we can prove this we will need some preliminary results.

Doob's upcrossing inequality

For a real sequence $(x_n)_{n \geq 0}$, for an interval $[a, b]$ we want to count the number of times (x_n) crosses below a or above b . Define $T_0(x) = 0$ and define for $k \geq 0$

$$S_{k+1}(x) = \inf\{n \geq T_k(x) : x_n \leq a\} \text{ the } (k+1)\text{st downcrossing}$$

$$T_{k+1}(x) = \inf\{n \geq S_{k+1}(x) : x_n \geq b\} \text{ the } (k+1)\text{st upcrossing.}$$

Also let $N_n([a, b], x) = \sup\{k \geq 0 : T_k(x) \leq n\}$, the number of up crossings up to time N . Then as $n \rightarrow \infty$, $N_n([a, b], x) \uparrow N([a, b], x) = \sup\{k \geq 0 : T_k(x) < \infty\}$.

Lemma. *Let $x = (x_n)_{n \geq 0}$ be a real sequence. Then x converges in $\overline{\mathbb{R}} = \mathbb{R} \cup \{\pm\infty\}$ if and only if for all $a < b$, $a, b \in \mathbb{Q}$ we have $N([a, b], x) < \infty$.*

Proof. If x converges then suppose there is $a < b$ with $N([a, b], x) = \infty$. Then

$$\liminf x_n \leq a < b \leq \limsup x_n$$

a contradiction.

Conversely, if x doesn't converge we have $\liminf x_n < \limsup x_n$ so there are $a < b$ (with $a, b \in \mathbb{Q}$) with $\liminf x_n < a < b < \limsup x_n$ and hence $N([a, b], x) = \infty$. \square

Now we can prove

Theorem (Doob's upcrossing inequality). *Let X be a supermartingale and $a < b$. Then for all n ,*

$$(b - a)\mathbb{E}[N_n([a, b], X)] \leq \mathbb{E}[(X_n - a)^-].$$

Proof. We have $(T_k)_{k \geq 0}, (S_k)_{k \geq 0}$ stopping times. Then

$$\sum_{k=1}^n (X_{T_k \wedge n} - X_{S_k \wedge n}) = \sum_{k=1}^{N_n([a, b], X)} \underbrace{(X_{T_k} - X_{S_k})}_{\geq b-a} + \underbrace{(X_n - X_{S_{N_n+1}})\mathbb{1}(S_{N_n+1} \leq n)}_{\geq (X_n - a) \vee 0 = -(X_n - a)^-}.$$

Note $T_k \wedge n, S_k \wedge n$ are stopping times with $T_k \wedge n \geq S_k \wedge n$. Then by the optional stopping theorem $\mathbb{E}[X_{T_k \wedge n}] \leq \mathbb{E}[X_{S_k \wedge n}]$. So taking expectations we have

$$0 \geq (b - a)\mathbb{E}[N_n] - \mathbb{E}[(X_n - a)^-].$$

\square

Now we are ready to prove

Theorem (Almost-sure martingale convergence theorem). *Let X be a supermartingale bounded in \mathcal{L}^1 , i.e. $\sup_{n \geq 0} \mathbb{E}[X_n] < \infty$. Then there exists a random variable $X_\infty \in \mathcal{L}^1(\mathcal{F}_\infty)$ where $\mathcal{F}_\infty = \sigma(\mathcal{F}_n : n \geq 0)$ such that $X_n \rightarrow X_\infty$ almost-surely as $n \rightarrow \infty$.*

Proof. Let $a, b \in \mathbb{Q}$ be such that $a < b$. Then

$$\begin{aligned} \mathbb{E}[N_n([a, b], X)] &\leq (b - a)^{-1} \mathbb{E}[(X_n - a)^-] \\ &\leq (b - a)^{-1} \mathbb{E}[|X_n| + a] \\ &\leq (b - a)^{-1} \left(\sup_{n \geq 0} \mathbb{E}[|X_n|] + 1 \right). \end{aligned}$$

We know $N_n([a, b], X) \uparrow N([a, b], X)$ as $n \rightarrow \infty$, so by monotone convergence, $\mathbb{E}[N([a, b], X)] < \infty$. Set

$$\Omega_0 = \bigcap_{\substack{a < b \\ a, b \in \mathbb{Q}}} \{N([a, b], X) < \infty\} \in \mathcal{F}_\infty$$

so $\mathbb{P}(\Omega_0) = 1$ as the intersection of almost-sure events. On Ω_0 , X converges by a previous lemma. Set

$$X_\infty = \begin{cases} \lim_{n \rightarrow \infty} X_n & \text{on } \Omega_0 \\ 0 & \text{on } \Omega \setminus \Omega_0 \end{cases}.$$

So X_∞ is \mathcal{F}_∞ -measurable, and $X_n \rightarrow X_\infty$ almost surely. Also

$$\mathbb{E}[|X_\infty|] = \mathbb{E}[\liminf_n |X_n|] \leq \liminf_n \mathbb{E}[|X_n|] < \infty$$

by Fatou. □

Corollary. *Let X be a positive super-martingale. Then X converges almost-surely.*

Proof. $\mathbb{E}[|X_n|] = \mathbb{E}[X_n] \leq \mathbb{E}[X_0]$. So apply the previous. □

Doob's inequalities

Theorem (Doob's maximal inequality). *Let X be a non-negative submartingale. Set $X_n^* = \sup_{0 \leq k \leq n} X_k$. Then for all $\lambda \geq 0$*

$$\lambda \mathbb{P}(X_n^* \geq \lambda) \leq \mathbb{E}[X_n \mathbb{1}(X_n^* \geq \lambda)] \leq \mathbb{E}[X_n].$$

Proof. Let $T = \inf\{k \geq 0 : X_k \geq \lambda\}$. Then T is a stopping time and $\{X_n^* \geq \lambda\} = \{T \leq n\}$. By the optional stopping theorem we have $\mathbb{E}[X_{T \wedge n}] \leq \mathbb{E}[X_n]$ and note

$$\begin{aligned} \mathbb{E}[X_n] &\geq \mathbb{E}[X_{T \wedge n}] = \mathbb{E}[X_T \mathbb{1}(T \leq n)] + \mathbb{E}[X_n \mathbb{1}(T > n)] \\ &\geq \lambda \mathbb{P}(T \leq n) + \mathbb{E}[X_n \mathbb{1}(T > n)]. \end{aligned}$$

Therefore

$$\lambda \mathbb{P}(X_n^* \geq \lambda) = \lambda \mathbb{P}(T \leq n) \leq \mathbb{E}[X_n \mathbb{1}(T \leq n)] = \mathbb{E}[X_n \mathbb{1}(X_n^* \geq \lambda)].$$

□

Theorem. *Doob's \mathcal{L}^p -inequality* Let $p > 1$ and let X be a martingale or a non-negative submartingale. Set $X_n^* = \sup_{0 \leq k \leq n} |X_k|$. Then

$$\|X_n^*\|_p \leq \frac{p}{p-1} \|X_n\|_p.$$

Proof. By Jensen's inequality it is enough to prove for X a non-negative submartingale. Let $k > 0$ and note

$$(y \wedge k)^p = \int_0^k p x^{p-1} \mathbb{1}(y \geq x) dx$$

so

$$\begin{aligned} \|X_n^* \wedge k\|_p^p &= \mathbb{E}[(X_n^* \wedge k)^p] \\ &= \mathbb{E} \left[\int_0^k p x^{p-1} \mathbb{1}(X_n^* \geq x) dx \right] \\ &= \int_0^k p x^{p-1} \mathbb{P}(X_n^* \geq x) dx && \text{(Fubini)} \\ &\leq \int_0^k p x^{p-1} x^{-1} \mathbb{E}[X_n \mathbb{1}(X_n^* \geq x)] dx && \text{(Doob's max inequality)} \\ &= \mathbb{E} \left[\int_0^k p x^{p-2} \mathbb{1}(X_n^* \geq x) dx X_n \right] && \text{(Fubini)} \\ &= \mathbb{E} \left[X_n \frac{p}{p-1} (X_n^* \wedge k)^{p-1} \right] \\ &\leq \frac{p}{p-1} \|X_n\|_p \|X_n^* \wedge k\|_p^{p-1}. && \text{(Hölder)} \end{aligned}$$

Therefore $\|X_n^* \wedge k\|_p \leq \frac{p}{p-1} \|X_n\|_p$. Taking $k \rightarrow \infty$ gives the result by monotone convergence. \square

Theorem (\mathcal{L}^p -convergence theorems). *Let X be a martingale, $p > 1$. The following are equivalent*

1. X is bounded in \mathcal{L}^p , i.e. $\sup_{n \geq 0} \|X_n\|_p < \infty$.
2. X converges almost-surely and in \mathcal{L}^p to a limit $X_\infty \in \mathcal{L}^p$.
3. There exists $Z \in \mathcal{L}^p$ such that $X_n = \mathbb{E}[Z|\mathcal{F}_n]$ almost-surely.

Proof. (1 \Rightarrow 2) If X is bounded in \mathcal{L}^p then it is bounded in \mathcal{L}^1 . Hence there exists X_∞ such that $X_n \rightarrow X_\infty$ almost-surely as $n \rightarrow \infty$. Furthermore

$$\mathbb{E}|X_\infty|^p = \mathbb{E}[\liminf_n |X_n|^p] \leq \liminf_n \mathbb{E}[|X_n|^p] < \infty \quad (\text{Fatou})$$

so $X_\infty \in \mathcal{L}^p$. Define $X_n^* = \sup_{0 \leq k \leq n} |X_k|$, $X_\infty^* = \sup_{k \geq 0} |X_k|$. Then $|X_n - X_\infty| \leq 2X_\infty^*$ for all n . By dominated convergence it is enough to show $X_\infty^* \in \mathcal{L}^p$. Doob's \mathcal{L}^p inequality gives

$$\|X_n^*\|_p \leq \frac{p}{p-1} \|X_n\|_p \leq \frac{p}{p-1} \sup_{n \geq 0} \|X_n\|_p.$$

So by monotone convergence $\|X_\infty^*\|_p < \infty$.

(2 \Rightarrow 3) Set $Z = X_\infty$. Need to show $X_n = \mathbb{E}[X_\infty|\mathcal{F}_n]$ almost-surely. We have for $m \geq n$ that

$$\begin{aligned} \|X_n - \mathbb{E}[X_\infty|\mathcal{F}_n]\|_p &= \|\mathbb{E}[X_m|\mathcal{F}_n] - \mathbb{E}[X_\infty|\mathcal{F}_n]\|_p \\ &\leq \|X_m - X_\infty\|_p \quad (\text{conditional Jensen}) \\ &\rightarrow 0 \text{ as } m \rightarrow \infty. \end{aligned}$$

(3 \Rightarrow 1) By conditional Jensen. \square

Proof. A martingale of the form $X_n = \mathbb{E}[Z|\mathcal{F}_n]$ for $Z \in \mathcal{L}^p$ is called a *martingale closed in \mathcal{L}^p* . \square

Corollary. *If $Z \in \mathcal{L}^p$, $X_n = \mathbb{E}[Z|\mathcal{F}_n]$ almost-surely then $X_n \rightarrow \mathbb{E}[Z|\mathcal{F}_\infty]$ almost-surely and in \mathcal{L}^p , where $\mathcal{F}_\infty = \sigma(\mathcal{F}_n : n \geq 0)$.*

Proof. By the theorem we have $X_n \rightarrow X_\infty$ almost-surely and in \mathcal{L}^p . We need to show $X_\infty = \mathbb{E}[Z|\mathcal{F}_\infty]$ almost-surely.

- X_∞ is certainly \mathcal{F}_∞ -measurable.

- So we check that for all $A \in \mathcal{F}_\infty$ we have $\mathbb{E}[Z\mathbb{1}(A)] = \mathbb{E}[X_\infty\mathbb{1}(A)]$. Note that $\bigcup_{n \geq 0} \mathcal{F}_n$ is a π -system generating \mathcal{F}_∞ so it suffices to check for A in this π -system. Indeed for such A , there exists $N \geq 0$ such that $A \in \mathcal{F}_N$. Now let $n \geq N$ so

$$\begin{aligned}\mathbb{E}[Z\mathbb{1}(A)] &= \mathbb{E}[\mathbb{E}[Z|\mathcal{F}_N]\mathbb{1}(A)] \\ &= \mathbb{E}[X_N\mathbb{1}(A)] \rightarrow \mathbb{E}[X_\infty\mathbb{1}(A)] \text{ as } n \rightarrow \infty.\end{aligned}$$

□

Uniform integrability

Recall that a collection $(X_i)_{i \in I}$ of random variables is said to be *uniformly integrable* if

$$\sup_{i \in I} \mathbb{E}[|X_i| \mathbb{1}(|X_i| > \alpha)] \rightarrow 0 \text{ as } \alpha \rightarrow \infty.$$

Equivalently, $(X_i)_{i \in I}$ is uniformly integrable (UI) if it is bounded in \mathcal{L}^1 and for all $\varepsilon > 0$ there exists $\delta > 0$ such that for all $A \in \mathcal{F}$ with $\mathbb{P}(A) < \delta$ we have

$$\sup_{i \in I} \mathbb{E}[|X_i| \mathbb{1}(A)] < \varepsilon.$$

Remark. If $(X_i)_{i \in I}$ is bounded in \mathcal{L}^p for $p > 1$ then it is uniformly integrable.

Lemma. Let $(X_n)_{n \geq 1}, X$ be in \mathcal{L}^1 and $X_n \rightarrow X$ almost-surely as $n \rightarrow \infty$. Then $X_n \rightarrow X$ in \mathcal{L}^1 if and only if $(X_n)_{n \geq 1}$ is uniformly integrable.

Proof. See Part II Probability & Measure. □

Theorem. Let $X \in \mathcal{L}^1$. The family $\{\mathbb{E}[X|\mathcal{G}] : \mathcal{G} \subseteq \mathcal{F} \text{ a sub-}\sigma\text{-algebra}\}$ is uniformly integrable.

Proof. We need to show that for all $\varepsilon > 0$, there exists λ large enough such that for any sub- σ -algebra $\mathcal{G} \subseteq \mathcal{F}$ we have

$$\mathbb{E}[\mathbb{E}[X|\mathcal{G}] \mathbb{1}(|\mathbb{E}[X|\mathcal{G}]| > \lambda)] < \varepsilon.$$

Indeed

$$\begin{aligned} \mathbb{E}[\mathbb{E}[X|\mathcal{G}] \mathbb{1}(|\mathbb{E}[X|\mathcal{G}]| > \lambda)] &\leq \mathbb{E}[\underbrace{\mathbb{E}[|X||\mathcal{G}]}_{\mathcal{G}\text{-meas}} \mathbb{1}(|\mathbb{E}[X|\mathcal{G}]| > \lambda)] \\ &= \mathbb{E}[|X| \mathbb{1}(|\mathbb{E}[X|\mathcal{G}]| > \lambda)]. \end{aligned}$$

Since $X \in \mathcal{L}^1$, there exists $\delta > 0$ such that if $A \in \mathcal{F}$ has $\mathbb{P}(A) < \delta$, then $\mathbb{E}[|X| \mathbb{1}(A)] < \varepsilon$. Then

$$\mathbb{P}(|\mathbb{E}[X|\mathcal{G}]| > \lambda) \leq \frac{\mathbb{E}[|\mathbb{E}[X|\mathcal{G}]|]}{\lambda} \leq \frac{\mathbb{E}[|X|]}{\lambda}.$$

So taking $\lambda = \mathbb{E}[|X|]/\delta$, we are done. \square

Definition. $X = (X_n)_{n \geq 0}$ is called a *UI [sub/super] martingale* if it is a [sub/super] martingale and $(X_n)_{n \geq 1}$ is uniformly integrable.

Example. Let X_1, X_2, \dots be iid with $\mathbb{P}(X_1 = 0) = \mathbb{P}(X_1 = 2) = 1/2$. Set $Y_0 = 1$ and $Y_n = X_1 X_2 \dots X_n$ for $n \geq 1$, so $(Y_n)_{n \geq 0}$ is a martingale and $\mathbb{E}[Y_n] = 1$ for all n . But $Y_n \rightarrow 0$ almost surely.

Theorem. Let X be a martingale. The following are equivalent

- X is UI;
- X converges almost surely in \mathcal{L}^1 to X_∞ as $n \rightarrow \infty$;
- There exists $Z \in \mathcal{L}^1$ such that $X_n = \mathbb{E}[Z|\mathcal{F}_n]$ for all n almost-surely.

Proof. (1 \Rightarrow 2) X is bounded in \mathcal{L}^1 , so by the martingale convergence theorem X converges almost-surely to X_∞ . Since X is also UI, $X_n \rightarrow X_\infty$ in \mathcal{L}^1 too.

(2 \Rightarrow 3) Set $Z = X_\infty$. We need to show $X_n = \mathbb{E}[X_\infty|\mathcal{F}_n]$ almost surely. Then for $m \geq n$

$$\begin{aligned} \|X_n - \mathbb{E}[X_\infty|\mathcal{F}_n]\|_1 &= \|\mathbb{E}[X_m - X_\infty|\mathcal{F}_n]\|_1 \\ &\leq \|X_m - X_\infty\|_1 \xrightarrow{m \rightarrow \infty} 0. \end{aligned}$$

(3 \Rightarrow 1) The previous theorem implies X is UI. \square

Remark. As before we get $X_\infty = \mathbb{E}[Z|\mathcal{F}_\infty]$ almost-surely since $\mathcal{F}_\infty = \sigma(\mathcal{F}_n : n \geq 0)$.

Remark. If X were a UI super/sub-martingale, then we would get $\mathbb{E}[X_\infty|\mathcal{F}_n] \leq X_n$ or $\geq X_n$ respectively.

If X is UI with $X_n \rightarrow X_\infty$, and T is a stopping time then

$$X_T = \sum_{n \geq 0} X_n \mathbb{1}(T = n) + X_\infty \mathbb{1}(T = \infty).$$

Theorem (Optional Stopping Theorem for UI Martingales). *Let X be a UI martingale and let S, T be stopping times with $S \leq T$. Then*

$$\mathbb{E}[X_T|\mathcal{F}_S] = X_S \text{ almost-surely.}$$

Proof. We know $X_n = \mathbb{E}[X_\infty|\mathcal{F}_n]$ almost-surely since X is UI. It suffices to prove that for any stopping time T , $\mathbb{E}[X_\infty|\mathcal{F}_T] = X_T$ almost-surely. Indeed, then we will have

$$\mathbb{E}[X_T|\mathcal{F}_S] = \mathbb{E}[\mathbb{E}[X_\infty|\mathcal{F}_T]|\mathcal{F}_S] = \mathbb{E}[X_\infty|\mathcal{F}_S] = X_S$$

by the tower property since $\mathcal{F}_S \subseteq \mathcal{F}_T$.

So we just establish $\mathbb{E}[X_\infty|\mathcal{F}_T] = X_T$ almost-surely. First we show $X_T \in \mathcal{L}^1$. We have

$$\begin{aligned} \mathbb{E}[|X_T|] &= \sum_{n \geq 0} \mathbb{E}[|X_n| \mathbb{1}(T = n)] + \mathbb{E}[|X_\infty| \mathbb{1}(T = \infty)] \\ &\leq \sum_{n \geq 0} \mathbb{E}[\mathbb{E}[|X_\infty||\mathcal{F}_n] \mathbb{1}(T = n)] + \mathbb{E}[|X_\infty| \mathbb{1}(T = \infty)] \quad (\text{Jensen}) \\ &= \sum_{n \geq 0} \mathbb{E}[|X_\infty| \mathbb{1}(T = n)] + \mathbb{E}[|X_\infty| \mathbb{1}(T = \infty)] \\ &= \mathbb{E}[|X_\infty|] < \infty. \end{aligned}$$

We have that X_T is \mathcal{F}_T -measurable so we need to show that for all $B \in \mathcal{F}_T$, $\mathbb{E}[X_\infty \mathbb{1}(B)] = \mathbb{E}[X_T \mathbb{1}(B)]$. Indeed

$$\begin{aligned} \mathbb{E}[X_T \mathbb{1}(B)] &= \sum_{n \geq 0} \mathbb{E}[X_n \underbrace{\mathbb{1}(T = n) \mathbb{1}(B)}_{\in \mathcal{F}_n}] + \mathbb{E}[X_\infty \mathbb{1}(B) \mathbb{1}(T = \infty)] \\ &= \sum_{n \geq 0} \mathbb{E}[X_\infty \mathbb{1}(T = n) \mathbb{1}(B)] + \mathbb{E}[X_\infty \mathbb{1}(B) \mathbb{1}(T = \infty)] \\ &= \mathbb{E}[X_\infty \mathbb{1}(B)]. \end{aligned}$$

□

Backwards martingales

Let $\mathcal{F} \supseteq \mathcal{G}_0 \supseteq \mathcal{G}_{-1} \supseteq \dots$ be a decreasing family of sub- σ -algebras of \mathcal{F} . We call $X = (X_n)_{n \geq 0}$ a *backwards martingale* if $X_0 \in \mathcal{L}^1$ and for all $n \geq 1$,

$\mathbb{E}[X_{n+1}|\mathcal{G}_n] = X_n$ almost-surely.

By the tower property, $\mathbb{E}[X_0|\mathcal{G}_n] = X_n$ for all $n \leq 0$ almost-surely. Since $X_0 \in \mathcal{L}^1$, a backwards martingale is automatically UI.

Theorem. *Let X be a backwards martingale with $X_0 \in \mathcal{L}^p$ for $p \in [1, \infty)$. Then $X_n \rightarrow X_{-\infty}$ almost-surely and in \mathcal{L}^p , where $X_{-\infty} = \mathbb{E}[X_0|\mathcal{G}_{-\infty}]$ for $\mathcal{G}_{-\infty} = \bigcap_{n \geq 0} \mathcal{G}_{-n}$.*

Proof. Set $\mathcal{F}_k = \mathcal{G}_{-n+k}$ for $0 \leq k \leq n$. This is an increasing filtration and $(X_{-n+k})_{0 \leq k \leq n}$ is a (\mathcal{F}_k) -martingale. Let $N_{-n}([a, b], X)$ be the number of up-crossings of $[a, b]$ between $-n$ and 0. Doob's upcrossing inequality gives

$$(b - a)\mathbb{E}[N_{-n}([a, b], X)] \leq \mathbb{E}[(X_0 - a)^-].$$

As before, we get $X_n \rightarrow X_{-\infty}$ as $n \rightarrow -\infty$ almost-surely. $X_{-\infty}$ is $\mathcal{G}_{-\infty}$ -measurable (since it's \mathcal{G}_{-n} -measurable for all $n \geq 0$, so measurable by the intersection). Since $X_0 \in \mathcal{L}^p$, we have $X_n \in \mathcal{L}^p$ for all $n \leq 0$ by Jensen. Also $X_{-\infty} \in \mathcal{L}^p$ by Fatou.

Now we need to show $X_n \rightarrow X_{-\infty}$ in \mathcal{L}^p . We have

$$\begin{aligned} |X_n - X_{-\infty}|^p &= |\mathbb{E}[X_0|\mathcal{G}_n] - \mathbb{E}[X_{-\infty}|\mathcal{G}_n]|^p \\ &\leq \mathbb{E}[|X_0 - X_{-\infty}|^p|\mathcal{G}_n] \end{aligned}$$

hence by a previous result, $(|X_n - X_{-\infty}|^p)_n$ is a UI family. Since $X_n \rightarrow X_{-\infty}$ almost-surely, we have \mathcal{L}^1 convergence of $|X_n - X_{-\infty}|^p$, i.e \mathcal{L}^p convergence of the X_n .

Finally we need to show $X_{-\infty} = \mathbb{E}[X_0|\mathcal{G}_{-\infty}]$ almost-surely. Let $A \in \mathcal{G}_{-\infty} = \bigcap_{n \leq 0} \mathcal{G}_n$ so $A \in \mathcal{G}_n$ for all $n \leq 0$. Then $\mathbb{E}[X_n \mathbb{1}(A)] = \mathbb{E}[X_0 \mathbb{1}(A)]$ for all n . Since $X_n \rightarrow X_{-\infty}$ in \mathcal{L}^1 we have $\mathbb{E}[X_{-\infty} \mathbb{1}(A)] = \mathbb{E}[X_0 \mathbb{1}(A)]$ and so $X_{-\infty} = \mathbb{E}[X_0|\mathcal{G}_{-\infty}]$. \square

Applications of martingales

Theorem (Kolmogorov's 0-1 Law). *Let $(X_n)_{n \geq 0}$ be iid and $\mathcal{F}_n = \sigma(X_k : k \geq n)$ be the tail σ -algebra. Take $\mathcal{F}_\infty = \bigcap_{n \geq 0} \mathcal{F}_n$. Then \mathcal{F}_∞ is trivial, i.e. for all $A \in \mathcal{F}_\infty$ we have $\mathbb{P}(A) \in \{0, 1\}$.*

Proof. Let $A \in \mathcal{F}_\infty$ and let $\mathcal{G}_n = \sigma(X_k : k \leq n)$ be the natural filtration of the X_n , and $\mathcal{G}_\infty = \sigma(\mathcal{G}_n : n \geq 0)$. Note $(\mathbb{E}[\mathbb{1}(A)|\mathcal{G}_n])_{n \geq 0}$ is a martingale and $\mathbb{E}[\mathbb{1}(A)|\mathcal{G}_n] \rightarrow \mathbb{E}[\mathbb{1}(A)|\mathcal{G}_\infty]$ almost-surely. Since $A \in \mathcal{F}_\infty$, we have $A \in \mathcal{F}_{n+1}$ and \mathcal{G}_n is independent of \mathcal{F}_{n+1} by independence of the X_n . So $\mathbb{E}[\mathbb{1}(A)|\mathcal{G}_n] = \mathbb{P}(A)$ almost-surely. Since $\mathcal{F}_\infty \subseteq \mathcal{G}_\infty$ we have $A \in \mathcal{G}_\infty$, we have $\mathbb{E}[\mathbb{1}(A)|\mathcal{G}_\infty] = \mathbb{1}(A)$ almost-surely. Therefore $\mathbb{P}(A) = \mathbb{1}(A)$ almost-surely, so $\mathbb{P}(A) \in \{0, 1\}$. \square

Theorem (Strong Law of Large Numbers). *Let (X_i) be an iid sequence in \mathcal{L}^1 with $\mu = \mathbb{E}[X_1]$. Define $S_n = X_1 + \dots + X_n$. Then $\frac{S_n}{n}$ converges almost-surely and in \mathcal{L}^1 to μ as $n \rightarrow \infty$.*

Proof. Define $\mathcal{G}_n = \sigma(S_n, S_{n+1}, \dots) = \sigma(S_n, X_{n+1}, \dots)$. For $n \leq -1$ let $M_n = \frac{S_{-n}}{-n}$. We will show $(M_n)_{n \leq -1}$ is a backwards martingale with respect to $(\mathcal{G}_{-n})_{n \leq -1}$. We have

$$\mathbb{E}[M_{m+1}|\mathcal{G}_{-m}] = \mathbb{E}\left[\frac{S_{-m-1}}{-m-1}|\mathcal{G}_{-m}\right].$$

Take $n = -m$ so this becomes

$$\begin{aligned} \mathbb{E}\left[\frac{S_{n-1}}{n-1}|\mathcal{G}_n\right] &= \mathbb{E}\left[\frac{S_{n-1}}{n-1}|S_n, X_{n+1}, \dots\right] \\ &= \mathbb{E}\left[\frac{S_n - X_n}{n-1}|S_n\right] && \text{(independence)} \\ &= S_n - \frac{\mathbb{E}[X_n|S_n]}{n-1} \\ &= S_n - \frac{S_n}{n-1} \\ &= \frac{S_n}{n} \\ &= M_m \end{aligned}$$

where we used the fact $\mathbb{E}[X_k|S_n] = \mathbb{E}[X_1|S_n]$ for all $k \in [n]$. Hence we have a backwards martingale, so $\frac{S_n}{n} \rightarrow Y$ almost-surely and in \mathcal{L}^1 for some Y by the Backwards Martingale Theorem.

To finish, we need to show $Y = \mu$ almost-surely. We have

$$Y = \lim_{n \rightarrow \infty} \frac{S_n}{n} = \lim_{n \rightarrow \infty} \frac{X_{k+1} + \dots + X_{k+n}}{n} \text{ for all } k.$$

Hence Y is $\sigma(X_{k+1}, \dots)$ measurable for all k . Hence Y is $\bigcap_{k \geq 0} \sigma(X_{k+1}, \dots)$ -measurable, so by Kolmogorov's 0-1 law Y is almost-surely constant. Since S_n/n converges to Y in \mathcal{L}^1 , $\lim_{n \rightarrow \infty} \mathbb{E}[S_n/n] = \mu = \mathbb{E}Y = Y$. \square

Theorem (Radon-Nikodym Theorem). *Let \mathbb{P} and Q be two probability measures on the space (Ω, \mathcal{F}) . Suppose \mathcal{F} is countably generated, i.e. there exist $(F_n)_{n \geq 1}$ such that $\mathcal{F} = \sigma(F_n : n \geq 1)$. The following are equivalent*

- $Q \ll \mathbb{P}$, i.e. for all $A \in \mathcal{F}$, $\mathbb{P}(A) = 0$ implies $Q(A) = 0$. We say Q is absolutely continuous with respect to \mathbb{P} ;
- For all $\varepsilon > 0$, there exists $\delta > 0$ such that if $A \in \mathcal{F}$ with $\mathbb{P}(A) < \delta$ then $Q(A) < \varepsilon$;
- There exists a non-negative random variable X such that $Q(A) = \mathbb{E}[X \mathbb{1}(A)]$ for all $A \in \mathcal{F}$.

Note. The general case where \mathcal{F} is not necessarily countably generated follows from this (see Williams).

Remark. X as in (3) is called a *version of the Radon-Nikodym derivative of Q with respect to \mathbb{P}* . We write $X = \frac{dQ}{d\mathbb{P}}$ on \mathcal{F} almost-surely.

Proof. (1 \Rightarrow 2) If 2 doesn't hold, there exists $\varepsilon > 0$ such that for all n there exists $A_n \in \mathcal{F}$ with $\mathbb{P}(A_n) \leq 1/n^2$ and $Q(A_n) \geq \varepsilon$. Then $\sum_{n \geq 1} \mathbb{P}(A_n) < \infty$, so by Borel-Cantelli we see $\mathbb{P}(A_n \text{ i.o.}) = 0$. Hence by (1), $Q(A_n \text{ i.o.}) = 0$. Since

$$\{A_n \text{ i.o.}\} = \bigcap_{n \geq 1} \bigcup_{k \geq n} A_k \implies Q(A_n \text{ i.o.}) = \lim_{n \rightarrow \infty} Q\left(\bigcup_{k \geq n} A_k\right) \geq \varepsilon$$

we have a contradiction.

(2 \Rightarrow 3) Define

$$\mathcal{A}_n = \{H_1 \cap \dots \cap H_n : H_i = F_i \text{ or } H_i = F_i^c \forall i\}$$

and $\mathcal{F}_n = \sigma(\mathcal{A}_n)$. Note the elements of \mathcal{A}_n are disjoint and define $X_n(\omega) = \sum_{A \in \mathcal{A}_n} \frac{Q(A)}{\mathbb{P}(A)} \mathbb{1}(\omega \in A)$. If $A \in \mathcal{F}_n$ we have $\mathbb{E}[X_n \mathbb{1}(A)] = Q(A) = \mathbb{E}[X_{n+1} \mathbb{1}(A)]$. Hence (X_n) is an (\mathcal{F}_n) -martingale.

We have $\mathbb{E}[X_n] = Q(\Omega) = 1$, so (X_n) is an \mathcal{L}^1 -bounded martingale and $X_n \rightarrow X_\infty$ almost-surely as $n \rightarrow \infty$. Furthermore, $\mathbb{P}(X_n \geq \lambda) \leq \frac{1}{\lambda}$ by Markov's inequality, so for any $\varepsilon > 0$, taking $\delta > 0$ as in (2) and setting $\lambda = 1/\delta$ we have

$$\mathbb{E}[X_n \mathbb{1}(X_n \geq \lambda)] = Q(X_n \geq \lambda) < \varepsilon$$

and so (X_n) is UI. Hence $X_n \rightarrow X_\infty$ in \mathcal{L}^1 . Define $\tilde{Q}(A) = \mathbb{E}[X_\infty \mathbb{1}(A)]$ for all $A \in \mathcal{F}$. Then if $A \in \bigcup_{n \geq 0} \mathcal{F}_n$, $A \in \mathcal{F}_n$ for some n and

$$Q(A) = \mathbb{E}[X_n \mathbb{1}(A)] = \mathbb{E}[X_\infty \mathbb{1}(A)] = \tilde{Q}(A).$$

Since $\bigcup_{n \geq 0} \mathcal{F}_n$ is a π -system generating \mathcal{F} , $Q = \tilde{Q}$ on \mathcal{F} .

(3 \Rightarrow 1) Trivial. □

Continuous-time Processes

So far, we have considered sequences of random variables $(X_n)_{n \geq 0}$ on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$. Equivalently, we have a map $X : (\omega, n) \rightarrow X_n(\omega)$. It follows that this map is actually measurable with respect to the product σ -algebra $\mathcal{F} \otimes \mathcal{P}(\mathbb{N})$. Our random variables will be taking values in $E = \mathbb{R}^d$.

We call $(X_t)_{t \in \mathbb{R}_+}$ a *stochastic process* if for all t , X_t is a random variable. However, the map $X : (\omega, t) \mapsto X_t(\omega)$ is not necessarily measurable on $\mathcal{F} \otimes \mathcal{B}(\mathbb{R}_+)$.

Proposition. If for all $\omega \in \Omega$, $(0, 1] \rightarrow \mathbb{R}^d$ defined by $t \mapsto X_t(\omega)$ is continuous, then $X : (\omega, t) \mapsto X_t(\omega)$ is $\mathcal{F} \otimes \mathcal{B}((0, 1])$ -measurable.

Proof. By continuity,

$$X_t(\omega) = \lim_{n \rightarrow \infty} \sum_{i=0}^{2^n-1} \mathbb{1}(t \in (k2^{-n}, (k+1)2^{-n}]) X_{k2^{-n}}(\omega).$$

Hence X is measurable as a limit of measurable functions. \square

It is enough (and unless stated otherwise we will always assume) that X is right-continuous and admits left-limits almost-everywhere. We call such processes *càdlàg*.

A *filtration* is an increasing family of σ -algebras $(\mathcal{F}_t)_{t \in \mathbb{R}_+}$, $\mathcal{F}_t \subseteq \mathcal{F}_{t'}$ for all $t \leq t'$. We say X is *adapted* if X_t is \mathcal{F}_t -measurable for all t . A random variable $T : \Omega \rightarrow [0, \infty]$ is called a *stopping time* if for all t , $\{T \leq t\} \in \mathcal{F}_t$.

Define $\mathcal{F}_T = \{A \in \mathcal{F} : A \cap \{T \leq t\} \in \mathcal{F}_t \forall t\}$.

For $A \in \mathcal{B}(\mathbb{R})$, $T_A = \inf\{t \geq 0 : X_t \in A\}$ is not always a stopping time. We have

$$\{T_A \leq t\} = \bigcup_{s \leq t} \{X_s \in A\}$$

which is not necessarily in \mathcal{F}_t as we have an uncountable union.

Example. Let

$$J = \begin{cases} 1 & \text{with probability } 1/2 \\ -1 & \text{with probability } 1/2 \end{cases}$$

and

$$X_t = \begin{cases} t & 0 \leq t \leq 1 \\ 1 + J(t-1) & t > 1 \end{cases}.$$

Let $A = (1, 2)$, then $\{T_A \leq 1\} \notin \mathcal{F}_1$.

We also define the *stopped process* $X_t^T = X_{T \wedge t}$.

Proposition. Let S and T be stopping times and X a càdlàg adapted process. Then

1. If $S \leq T$, then $\mathcal{F}_S \subseteq \mathcal{F}_T$;
2. $S \wedge T$ is a stopping time;
3. $X_T \mathbb{1}(T < \infty)$ is \mathcal{F}_T -measurable;
4. X^T is adapted.

Proof. (1) and (2) are obvious and (4) follows from (3) since $X_{T \wedge t}$ is $\mathcal{F}_{T \wedge t}$ -measurable and $\mathcal{F}_{T \wedge t} \subseteq \mathcal{F}_t$. So we just prove (3).

We claim a random variable Z is \mathcal{F}_T -measurable if and only if $Z \mathbb{1}(T \leq t)$ is \mathcal{F}_t -measurable for all t . Indeed, if Z is \mathcal{F}_T -measurable then this is immediate by definition of \mathcal{F}_T .

Conversely, suppose $Z \mathbb{1}(T \leq t)$ is \mathcal{F}_t -measurable for all t . If $Z = c \mathbb{1}(A)$ for some $A \in \mathcal{F}$ it is clear. This extends to simple $Z = \sum_{i=1}^n c_i \mathbb{1}(A_i)$, $c_i > 0$, $A_i \in \mathcal{F}$. So writing $Z \geq 0$ as a limit of simple functions $2^{-n} \lfloor 2^n Z \rfloor \wedge n$, we are done.

Now we show $X_T \mathbb{1}(T \leq t)$ is \mathcal{F}_t measurable for all t . Since

$$X_T \mathbb{1}(T \leq t) = X_T \mathbb{1}(T < t) + \underbrace{X_t \mathbb{1}(T = t)}_{\mathcal{F}_t\text{-measurable}}$$

it suffices to show $X_T \mathbb{1}(T < t)$ is \mathcal{F}_t -measurable. Define $T_n = 2^{-n} \lceil 2^n T \rceil$. These are stopping times, since

$$\begin{aligned} \{T_n \leq t\} &= \{\lceil 2^n T \rceil \leq 2^n t\} = \{2^n T \leq \lfloor 2^n t \rfloor\} \\ &= \{T \leq 2^{-n} \lfloor 2^n t \rfloor\} \in \mathcal{F}_{2^{-n} \lfloor 2^n t \rfloor} \subseteq \mathcal{F}_t. \end{aligned}$$

By the càdlàg property, $X_T \mathbb{1}(T < t) = \lim_{n \rightarrow \infty} X_{T_n \wedge t} \mathbb{1}(T < t)$. T_n takes values in $\mathcal{D}_n = \{k 2^{-n} : k \in \mathbb{N}\}$. Note

$$X_{T_n \wedge t} \mathbb{1}(T < t) = \sum_{\substack{d \in \mathcal{D}_n \\ d \leq t}} \underbrace{X_d \mathbb{1}(T_n = d) \mathbb{1}(T < t)}_{\mathcal{F}_t\text{-measurable}} + \underbrace{X_t \mathbb{1}(T_n = t) \mathbb{1}(T < t)}_{\mathcal{F}_t\text{-measurable}}.$$

Hence $X_T \mathbb{1}(T < t)$ is \mathcal{F}_t -measurable as a limit of \mathcal{F}_t -measurable functions. \square

Proposition. Let X be continuous and adapted, and let A be a closed set. Then $T_A = \inf\{t \geq 0 : X_t \in A\}$ is a stopping time.

Proof. It suffices to show

$$\{T_A \leq t\} = \left\{ \inf_{\substack{s \in \mathbb{Q} \\ s \leq t}} d(X_s, A) = 0 \right\}$$

where $d(x, A) = \inf_{a \in A} |x - a|$. Suppose $T_A = s \leq t$. Then there exists a sequence $(s_n)_{n \geq 1}$ with $s_n \downarrow s$ such that $X_{s_n} \in A$ by definition of T_A . Since A is closed, this means $d(X_{s_n}, A) = 0$. By continuity $X_{s_n} \rightarrow X_s$ as $n \rightarrow \infty$, so $d(X_s, A) = 0$, implying $X_s = X_{T_A} \in A$. By continuity of X and d , there exists a sequence $(q_n)_{n \geq 1}$ of rationals with $q_n \uparrow s$ such that $d(X_{q_n}, A) \rightarrow 0$, and hence $\inf_{s \in \mathbb{Q}} d(X_s, A) = 0$.

If $\inf_{s \leq t} d(X_s, A) = 0$, then there is a sequence $(s_n)_{n \geq 1}$ of rationals with $s_n \leq t$ such that $d(X_{s_n}, A) \rightarrow 0$ as $n \rightarrow \infty$. So there is a convergent subsequence s_{n_k} of s_n , converging to some $s \leq t$ such that $d(X_{s_{n_k}}, A) \rightarrow 0$. Thus by continuity $d(X_s, A) = 0$, and since A is closed, $X_s \in A$ and $T_A \leq t$. \square

Define $\mathcal{F}_{t+} = \bigcap_{s > t} \mathcal{F}_s$, a σ -algebra. If for all t , $\mathcal{F}_{t+} = \mathcal{F}_t$, we say that (\mathcal{F}_t) is right-continuous.

Proposition. Let X be a continuous process and A be an open set. Then $T_A = \inf\{t \geq 0 : X_t \in A\}$ is a stopping time with respect to (\mathcal{F}_{t+})

Proof. We need to show that for all t , $\{T_A \leq t\} \in \mathcal{F}_{t+}$. Note

$$\{T_A < s\} = \bigcup_{\substack{q \in \mathbb{Q} \\ q < s}} \underbrace{\{X_q \in A\}}_{\in \mathcal{F}_s} \in \mathcal{F}_s.$$

Also

$$\{T_A \leq t\} = \bigcap_n \{T_A < t + 1/n\} \in \mathcal{F}_{t+1/n} \quad \forall n$$

so $\{T_A \leq t\} \in \mathcal{F}_{t+}$. □

A stochastic process $(X_t)_{t \geq 0}$ takes values in $\{f : f : \mathbb{R}_+ \rightarrow E\}$ (for us usually, $E = \mathbb{R}^d$). Denote by $C(\mathbb{R}_+, E)$ the space of continuous $f : \mathbb{R}_+ \rightarrow E$ and by $D(\mathbb{R}_+, E)$ the space of càdlàg $f : \mathbb{R}_+ \rightarrow E$.

We will endow C, D with the product σ -algebra that makes all projections $\pi_t : f \mapsto f(t)$ measurable for all t . This σ -algebra is generated by the cylinder sets $\{\bigcap_{s \in J} \{f_s \in A_s\} : J \text{ finite}, A_s \in \mathcal{B}\}$. For A in the product σ -algebra we write $\mu(A) = \mathbb{P}(X \in A)$, and we call μ the law of X .

For every finite subset $J \subseteq \mathbb{R}_+$, write μ_J for the law of $(X_t, t \in J)$. The measures $(\mu_J)_J$ are called the finite dimensional marginals of X . The (μ_J) completely characterise the law of X . This follows because $\{\bigcap_{s \in J} \{X_s \in A_s\} : J \text{ finite}, A_s \in \mathcal{B}(\mathbb{R}_+)\}$ is a π -system generating the σ -algebra on which μ is determined by the (μ_J) .

Example. Let $X_t = 0$ for all $t \in [0, 1]$, let $U \sim \text{Uniform}[0, 1]$ and $X'_t = \mathbb{1}(U = t)$ for $t \in [0, 1]$. Both of these have the same finite dimensional marginals, but the two processes are different, since $\mathbb{P}(X_t = 0 \forall t \in [0, 1]) = 1$ while $\mathbb{P}(X'_t = 0 \forall t \in [0, 1]) = 0$. However $\mathbb{P}(X_t = X'_t) = 1$ for all $t \in [0, 1]$.

Definition. Let X and X' be two processes on $(\Omega, \mathcal{F}, \mathbb{P})$. We say X' is a *version* of X if $\mathbb{P}(X_t = X'_t) = 1$ for all t .

Definition. Given our filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$, set \mathcal{N} to be the collection of sets of measure 0. Define

$$\tilde{\mathcal{F}}_t = \sigma(\mathcal{F}_{t+}, \mathcal{N}).$$

If for all t , $\mathcal{F}_t = \tilde{\mathcal{F}}_t$, we say that (\mathcal{F}_t) satisfies the *usual conditions* (u.c).

Theorem (Martingale regularisation theorem). *Let $(X_t)_{t \geq 0}$ be a martingale with respect to (\mathcal{F}_t) . Then there exists a càdlàg process \tilde{X} satisfying $\mathbb{P}(X_t = \mathbb{E}[\tilde{X}_t | \mathcal{F}_t]) = 1$ for all t , and \tilde{X} is a martingale with respect to $(\tilde{\mathcal{F}}_t)$.*

Remark. If (\mathcal{F}_t) satisfies the usual conditions, then \tilde{X} is a càdlàg version of X .

Lemma. Let $f : \mathbb{Q}_+ \rightarrow \mathbb{R}$ be such that for all $I \subseteq \mathbb{Q}_+$ bounded, f is bounded on I , and for any $a, b \in \mathbb{Q}$ with $a < b$,

$$N([a, b], I, f) < \infty$$

where $N([a, b], I, f)$ is equal to

$$\sup\{n \geq 0 : \exists 0 < s_1 < t_1 < \dots < s_n < t_n, s_i, t_i \in I, f(s_i) < a, f(t_i) > b\}.$$

Then for all $t \in \mathbb{R}_+$, the limits

$$\lim_{\substack{s \uparrow t \\ s \in \mathbb{Q}_+}} f(s) \text{ and } \lim_{\substack{s \downarrow t \\ s \in \mathbb{Q}_+}} f(s)$$

exist, and are finite.

Proof. Let $s_n \downarrow t$, $(f(s_n))$ will converge by the finite upcrossing proof. Let $s_n \downarrow t$ and $t_n \downarrow t$ and combine them to get a decreasing sequence, implying $\lim f(s_n) = \lim f(t_n)$. Since f is bounded, these limits are finite. \square

Proof of martingale regularisation theorem. We aim to define $\tilde{X}_t = \lim_{\substack{s \downarrow t \\ s \in \mathbb{Q}_+}} X_s$

on a set of measure 1 and $\tilde{X}_t = 0$ otherwise. Steps:

1. Show that the limit exists and is finite;
2. Show \tilde{X} is $\tilde{\mathcal{F}}$ -measurable and $X_t = \mathbb{E}[\tilde{X}_t | \mathcal{F}_t]$ almost-surely;
3. Show \tilde{X} satisfies the martingale property;
4. Show \tilde{X} is càdlàg.

Step 1: Let I be a bounded subset of \mathbb{Q}_+ . We need to show $\mathbb{P}(\sup_{t \in I} |X_t| < \infty) = 1$. We have $\sup_{t \in I} |X_t| = \sup_{J \subseteq I} \sup_{t \in J} |X_t|$. Let $J = \{j_1, \dots, j_n\} \subseteq I$ with $j_1 < \dots < j_n$ and $K > \sup_{\text{finite}} I$. Then

$$\lambda \mathbb{P}(\sup_{t \in J} |X_t| \geq \lambda) \leq \mathbb{E}[|X_{j_n}|] \leq \mathbb{E}[|X_K|]$$

by Doob's maximal inequality (since $(X_t)_{t \in J}$ is a discrete-time martingale). Taking limits as $J \uparrow I$, we have $\lambda \mathbb{P}(\sup_{t \in I} |X_t| \geq \lambda) \leq \mathbb{E}[|X_K|]$. Hence $\mathbb{P}(\sup_{t \in I} |X_t| < \infty) = 1$.

For $M \in \mathbb{N}$, define $I_M = \mathbb{Q}_+ \cap [0, M]$. Then

$$\mathbb{P}\left(\bigcap_{M \in \mathbb{N}} \left\{\sup_{t \in I_M} |X_t| < \infty\right\}\right) = 1.$$

Let $a, b \in \mathbb{Q}$ be such that $a < b$, $I \subseteq \mathbb{Q}_+$ bounded. Then

$$N([a, b], I, X) = \sup_{\substack{J \subseteq I \\ J \text{ finite}}} N([a, b], J, X).$$

Write $J = \{a_1, \dots, a_n\}$ where $a_1 < a_2 < \dots < a_n$ and take $K > \sup I$. Then (X_{a_i}) is a discrete-time martingale so

$$(b - a)\mathbb{E}[N([a, b], J, X)] \leq \mathbb{E}[(X_{a_n} - a)^-] \leq \mathbb{E}[(X_K - a)^-]$$

by Doob's upcrossing inequality. By monotone convergence we get

$$(b - a)\mathbb{E}[N([a, b], I, X)] < \infty.$$

Let $M \in \mathbb{N}$ and $I_M = \mathbb{Q}_+ \cap [0, M]$. Define

$$\Omega_0 = \bigcap_{M \in \mathbb{N}} \bigcap_{\substack{a < b \\ a, b \in \mathbb{Q}}} \{N([a, b], I_M, X) < \infty\} \cap \left\{ \sup_{t \in I_M} |X_t| < \infty \right\}.$$

Then on Ω_0 , by the previous lemma we have that $\lim_{\substack{s \downarrow t \\ s \in \mathbb{Q}}} X_s$ exists. Furthermore we have $\mathbb{P}(\Omega_0) = 1$.

So define

$$\tilde{X}_t = \begin{cases} \lim_{\substack{s \downarrow t \\ s \in \mathbb{Q}}} X_s & \text{on } \Omega_0 \\ 0 & \text{otherwise} \end{cases}.$$

Step 2: Then \tilde{X}_t is measurable with respect to $\tilde{\mathcal{F}}_t = \sigma(\mathcal{F}_{t+}, \mathcal{N})$ by definition.

Let $t_n \downarrow t$, $t_n \in \mathbb{Q}$. Then $\tilde{X}_t = \lim_{n \rightarrow \infty} X_{t_n}$ almost-surely. Note $(X_{t_n})_{n \geq 0}$ is a backwards martingale with respect to $(\mathcal{F}_{t_n})_{n \geq 0}$. Hence by the backwards martingale convergence theorem, (X_{t_n}) converges almost surely and in \mathcal{L}^1 . So

$$X_t = \mathbb{E}[X_{t_n} | \mathcal{F}_t] \rightarrow \mathbb{E}[\tilde{X}_t | \mathcal{F}_t] \text{ in } \mathcal{L}^1.$$

Hence $X_t = \mathbb{E}[\tilde{X}_t | \mathcal{F}_t]$ almost-surely.

Step 3: First we'll show $\mathbb{E}[X_t | \mathcal{F}_{s+}] = \tilde{X}_s$ almost-surely whenever $s < t$.

Claim: for any random variable X and \mathcal{G} a sub- σ -algebra we have $\mathbb{E}[X | \sigma(\mathcal{G}, \mathcal{N})] = \mathbb{E}[X | \mathcal{G}]$. Proof: exercise (consider a suitable π -system).

So if we can show $\mathbb{E}[X_t | \mathcal{F}_{s+}] = \tilde{X}_s$, the martingale follows from this claim immediately since the claim says $\mathbb{E}[X_t | \tilde{\mathcal{F}}_s] = \mathbb{E}[X_t | \mathcal{F}_{s+}] = \tilde{X}_s$ almost-surely, and then we can apply the tower law.

Now we show $\mathbb{E}[X_t | \mathcal{F}_{s+}] = \tilde{X}_s$ for $s < t$. Indeed let $s_n \downarrow s$, $s_n \in \mathbb{Q}_+$, $s_0 < t$. Then $\mathbb{E}[X_t | \mathcal{F}_{s_n}]$ is a backwards martingale, so converges a.s. and in \mathcal{L}^2 to $\mathbb{E}[X_t | \mathcal{F}_{s+}]$. But $\mathbb{E}[X_t | \mathcal{F}_{s_n}] = X_{s_n}$ and $X_{s_n} \rightarrow \tilde{X}_s$ a.s., so $\tilde{X}_s = \mathbb{E}[X_t | \mathcal{F}_{s+}]$ a.s.

Step 4: We will show \tilde{X} is right continuous. Suppose not, then there exists $\omega \in \Omega_0$ and some t such that $\tilde{X}(\omega)$ is not right-continuous at t , i.e there exists $s_n \downarrow t$ and some $\varepsilon > 0$ such that $|\tilde{X}_{s_n} - \tilde{X}_t| \geq \varepsilon$ for all n . By the definition of \tilde{X} , there exists (s'_n) such that $s'_n > s_n$ for all n , $s'_n \in \mathbb{Q}_+$, and $s'_n \downarrow t$ with $|\tilde{X}_{s_n} - X_{s'_n}| \leq \varepsilon/2$. So $|X_{s'_n} - \tilde{X}_t| \geq \varepsilon/2$, a contradiction since $s'_n \downarrow t$ and $s'_n \in \mathbb{Q}_+$. \square

Example. Let ξ, η be independent, taking values ± 1 with equal probability. Define

$$X_t = \begin{cases} 0 & t < 1 \\ \xi & t = 1 \\ \xi + \eta & t > 1 \end{cases}$$

and $\mathcal{F}_t = \sigma(X_s : s \leq t)$. Then X is a \mathcal{F} -martingale. We have that \tilde{X} satisfies $X_t = \mathbb{E}[\tilde{X}_t | \mathcal{F}_t]$. So we can see

$$\tilde{X}_t = \begin{cases} 0 & t < 1 \\ \xi + \eta & t \geq 1 \end{cases}.$$

Noting that $\mathcal{F}_1 = \sigma(\xi)$ and $\mathcal{F}_t = \sigma(\xi, \eta)$ for $t > 1$. Clearly \tilde{X} is càdlàg with respect to \tilde{F} , and note $\mathcal{F}_{1+} = \sigma(\xi, \eta)$. \mathcal{F} is not right-continuous so \tilde{X} is not a version of X .

Theorem (Almost-sure Martingale Convergence Theorem). *Let X be a càdlàg martingale bounded in \mathcal{L}^1 . Then $X_t \rightarrow X_\infty$ almost-surely as $t \rightarrow \infty$ with $X_\infty \in \mathcal{L}^1(\mathcal{F}_\infty)$.*

Proof. Take $I_M = \mathbb{Q}_+ \cap [0, M]$ we have (considering sequences and Doob's upcrossing inequality)

$$(b - a)\mathbb{E}[N([a, b], I_M, X)] \leq a + \sup_{t \geq 0} \mathbb{E}[|X_t|]$$

hence $N([a, b], \mathbb{Q}_+, X) < \infty$ almost-surely for all $a < b$. Define

$$\Omega_0 = \bigcap_{\substack{a < b \\ a, b \in \mathbb{Q}}} \{N([a, b], \mathbb{Q}_+, X) < \infty\}$$

so $\mathbb{P}(\Omega_0) = 1$ and on Ω_0 , $\lim_{q \rightarrow \infty, q \in \mathbb{Q}} X_q$ exists and is finite. Define $X_\infty = \lim_{q \rightarrow \infty, q \in \mathbb{Q}} X_q$ on Ω_0 .

Then for all $\varepsilon > 0$ there exists q_0 such that $|X_q - X_\infty| \leq \varepsilon/2$ for all $q \in (q_0, \infty) \cap \mathbb{Q}$. Let $t > q_0$, then there exists $q > t$ with $q \in \mathbb{Q}$ such that $|X_t - X_q| \leq \varepsilon/2$ by right-continuity. Hence $|X_t - X_\infty| \leq \varepsilon$. \square

Theorem (Doob's Maximal Inequality). *Let X be a càdlàg martingale, $X_t^* = \sup_{s \leq t} |X_s|$. Then for all $\lambda \geq 0$,*

$$\lambda \mathbb{P}(X_t^* \geq \lambda) \leq \mathbb{E}[|X_t| \mathbb{1}(X_t^* \geq \lambda)] \leq \mathbb{E}[|X_t|].$$

Proof. We have

$$\sup_{s \leq t} |X_s| = \sup_{s \in \{t\} \cup (\mathbb{Q}_+ \cap [0, t])} |X_s|$$

and use the beginning of the proof of the martingale regularisation theorem. \square

Note. The \mathcal{L}^p convergence theorems etc hold in the same way for continuous càdlàg martingales.

Theorem (Optional Stopping Theorem). *Let X be a càdlàg UI martingale. Then for all $S \leq T$ stopping times,*

$$\mathbb{E}[X_T | \mathcal{F}_S] = X_S \text{ a.s.}$$

Proof. Let $T_n = 2^{-n} \lceil 2^n T \rceil$ and $S_n = 2^{-n} \lceil 2^n S \rceil$, so $T_n \downarrow T$ and $S_n \downarrow S$. We need to show that for $A \in \mathcal{F}_S$ we have $\mathbb{E}[X_T \mathbb{1}(A)] = \mathbb{E}[X_S \mathbb{1}(A)]$. We have $X_{T_n} \rightarrow X_T$ and $X_{S_n} \rightarrow X_S$ almost-surely by right-continuity. We have $X_{T_n} = \mathbb{E}[X_\infty | \mathcal{F}_{T_n}]$ by a discrete result, so (X_{T_n}) is UI, giving $X_{T_n} \rightarrow X_T$ and $X_{S_n} \rightarrow X_S$ in \mathcal{L}^1 as well. By the discrete optional stopping theorem, $\mathbb{E}[X_{T_n} | \mathcal{F}_{S_n}] = X_{S_n}$ a.s. For $A \in \mathcal{F}_S$ we have $A \in \mathcal{F}_{S_n}$ (check), so

$$\mathbb{E}[X_{T_n} \mathbb{1}(A)] = \mathbb{E}[X_{S_n} \mathbb{1}(A)]$$

and taking limits we're done. □

Proposition (Kolmogorov's continuity criterion). Let $\mathcal{D}_n = \{k2^{-n} : 0 \leq k \leq 2^n\}$, $\mathcal{D} = \bigcup_{n \geq 0} \mathcal{D}_n$. Let $(X_t)_{t \in \mathcal{D}}$ be a stochastic process taking real values. Suppose there exists $\varepsilon > 0$, $p > 0$, $c > 0$ such that

$$\mathbb{E}[|X_t - X_s|^p] \leq c|t - s|^{1+\varepsilon} \quad \forall s, t \in \mathcal{D}.$$

Then for every $\alpha \in (0, \varepsilon/p)$, the process X is α -Hölder continuous, i.e there exists a random variable $K_\alpha < \infty$ such that $|X_t - X_s| \leq K_\alpha |t - s|^\alpha$ for all $s, t \in \mathcal{D}$.

Proof. Note that

$$\mathbb{P}(|X_{k2^{-n}} - X_{(k+1)2^{-n}}| \geq 2^{-n\alpha}) \leq 2^{n\alpha p} c 2^{-n(1+\varepsilon)} \quad (\text{Markov})$$

so

$$\mathbb{P}\left(\max_{0 \leq k \leq 2^n} |X_{k2^{-n}} - X_{(k+1)2^{-n}}| \geq 2^{-n\alpha}\right) \leq c 2^{n\alpha p - n\varepsilon}$$

and therefore summing over n and applying Borel-Cantelli,

$$\max_{0 \leq k \leq 2^n} |X_{k2^{-n}} - X_{(k+1)2^{-n}}| \leq 2^{-n\alpha} \text{ for all } n \text{ sufficiently large.}$$

Hence

$$\sup_{n \geq 0} \max_{0 \leq k \leq 2^n} \frac{|X_{k2^{-n}} - X_{(k+1)2^{-n}}|}{2^{-n\alpha}} \leq M < \infty$$

for some random variable M . Now we show there exists M' with $|X_t - X_s| \leq M'|t - s|^\alpha$. Suppose $s < t$, $s, t \in \mathcal{D}$ and let r be the unique integer such that $2^{-(r+1)} < t - s \leq 2^{-r}$. Then there exists k such that $s < k2^{-(r+1)} < t$, and set $a = k2^{-(r+1)}$. Then $t - a \leq 2^{-r}$ so

$$\begin{aligned} t - a &= \sum_{j \geq r+1} \frac{x_j}{2^j}, \quad x_j \in \{0, 1\} \\ a - s &= \sum_{j \geq r+1} \frac{y_j}{2^j}, \quad y_j \in \{0, 1\}. \end{aligned}$$

We can write $[s, t)$ as a disjoint union of dyadic intervals, each of them having length some 2^{-n} for $n \geq r + 1$, and each interval of length 2^{-n} will appear at

most twice. Hence

$$\begin{aligned}
 |X_t - X_s| &\leq \sum_{\substack{d,n \\ d \text{ endpoint of} \\ \text{dyadic interval} \\ \text{of length } 2^{-n}}} |X_d - X_{d+2^{-n}}| \\
 &\leq \sum_{d,n} 2^{-n\alpha} M \\
 &\leq 2M \sum_{n \geq r+1} 2^{-n\alpha} \\
 &= 2M \frac{2^{-(r+1)\alpha}}{1 - 2^{-\alpha}} \\
 &\leq \frac{2M}{1 - 2^{-\alpha}} |t - s|^\alpha.
 \end{aligned}$$

□

Weak convergence

Let (M, d) be a metric space endowed with its Borel σ -algebra.

Definition. Let (μ_n) be a sequence of probability measures on M . We say (μ_n) converges weakly to a measure μ , writing $\mu_n \Rightarrow \mu$ as $n \rightarrow \infty$, if $\mu_n(f) \rightarrow \mu(f)$ for all $f : M \rightarrow \mathbb{R}$ continuous and bounded.

Remark. Taking $f = 1$ gives $\mu(f) = 1$, so μ is necessarily a probability measure.

Example. Let (x_n) be a sequence in M with $x_n \rightarrow x$. Then $\delta_{x_n} \Rightarrow \delta_x$. Indeed $\delta_{x_n}(f) = f(x_n) \rightarrow f(x) = \delta_x(f)$ by continuity of f .

Example. Let $M = [0, 1]$, endowed with the Borel σ -algebra. Then defining $\mu_n = \frac{1}{n} \sum_{0 \leq k \leq n} \delta_{k/n}$, we have that μ_n converges weakly to the Lebesgue measure. Indeed,

$$\mu_n(f) = \frac{1}{n} \sum_{0 \leq k \leq n} f(k/n)$$

which is the Riemann sum of f , converging to $\int_0^1 f(x) dx$.

Example. Let $\mu_n = \delta_{1/n}$. Then $\mu_n \Rightarrow \delta_0$. Take $A = (0, 1)$, so $\mu_n(A) = 1$ for all n , but $\mu(A) = 0$, so $\mu_n(A) \not\rightarrow \mu(A)$.

Theorem. Let (μ_n) be a sequence of probability measures on (M, d) . The following are equivalent:

1. $\mu_n \Rightarrow \mu$;
2. For all open $G \subseteq M$, $\liminf_n \mu_n(G) \geq \mu(G)$;

3. For all closed $A \subseteq M$, $\limsup_n \mu_n(A) \leq \mu(A)$;

4. If A has $\mu(\partial A) = 0$, then $\mu_n(A) \rightarrow \mu(A)$.

Proof.

- (1 \Rightarrow 2) Let G be open with $G^c \neq \emptyset$ (empty case is trivial). Then for $M > 0$ define $f_M(x) = 1 \wedge (Md(x, G^c)) \leq \mathbb{1}(x \in G)$. Also $f_M(x) \uparrow \mathbb{1}(x \in G)$ as $M \rightarrow \infty$ and f_M is bounded and continuous. Hence $\mu_n(f_M) \rightarrow \mu(f_M)$ as $n \rightarrow \infty$. Also

$$\liminf_n \mu_n(G) \geq \liminf_n \mu_n(f_M) = \mu(f_M) \rightarrow \mu(f)$$

where the last limit follows by monotone convergence.

- (2 \Longleftrightarrow 3) Follows by taking complements.
- (2,3 \Rightarrow 4) We have

$$0 = \mu(\partial A) = \mu(\overline{A} \setminus \text{int}(A))$$

so $\mu(\overline{A}) = \mu(A) = \mu(\text{int}(A))$. Then by 2,3 we have

$$\begin{aligned} \liminf_n \mu_n(\text{int}(A)) &\geq \mu(\text{int}(A)) = \mu(A) \\ \limsup_n \mu_n(\overline{A}) &\leq \mu(\overline{A}) = \mu(A). \end{aligned}$$

- (4 \Rightarrow 1) We need to show $\mu_n(f) \rightarrow \mu(f)$ for all f continuous and bounded. Let $K > \sup |f|$ and suppose $f \geq 0$. Note

$$\begin{aligned} \mu_n(f) &= \int_M f(x) d\mu_n(x) = \int_M \left(\int_0^K \mathbb{1}(t \leq f(x)) dt \right) d\mu_n(x) \\ &= \int_0^K \mu_n(f \geq t) dt. \end{aligned}$$

It suffices to show $\mu_n(f \geq t) \rightarrow \mu(f \geq t)$ for almost-all t by dominated convergence. Note that $\{f \geq t\} = f^{-1}([t, \infty))$ is closed by continuity of f , so $\overline{\{f \geq t\}} = \{f \geq t\}$. Hence $\partial\{f \geq t\} \subseteq \{f = t\}$. We claim there exist at most a countable number of t such that $\mu(f = t) > 0$.

Indeed note $\{t : \mu(f = t) > 0\} = \bigcup_n \{t : \mu(f = t) \geq 1/n\}$ and $\{t : \mu(f = t) \geq 1/n\}$ has cardinality at most n , so $\{t : \mu(f = t) > 0\}$ is countable as a countable union of countable sets.

□

Consider the case $M = \mathbb{R}$ and let μ be a probability measure on \mathbb{R} . We define the distribution function of μ , $F_\mu : \mathbb{R} \rightarrow [0, 1]$ by $F_\mu(x) = \mu((-\infty, x])$.

Proposition. Let (μ_n) be a sequence of probability measures on \mathbb{R} . The following are equivalent

- (a) $\mu_n \Rightarrow \mu$ as $n \rightarrow \infty$;
- (b) $F_{\mu_n}(x) \rightarrow F(x)$ for all $x \in \mathbb{R}$ such that F_μ is continuous at x .

Proof. (a \Rightarrow b) Let x be a continuity point of F_μ . Then $F_{\mu_n}(x) = \mu_n((-\infty, x])$. Note that

$$\mu(\partial(-\infty, x]) = \mu(\{x\}) = \mu((-\infty, x]) - \lim_{n \rightarrow \infty} \mu((-\infty, x - 1/n]) = 0$$

by continuity of F_μ at x . By a previous proposition this implies $\mu_n((-\infty, x]) \rightarrow \mu((-\infty, x])$.

(b \Rightarrow a) Let G be an open set in \mathbb{R} . Then $G = \bigcup_k (a_k, b_k)$ for disjoint intervals (a_k, b_k) . Then

$$\begin{aligned} \liminf_n \mu_n(G) &= \liminf_n \sum_k \mu_n((a_k, b_k)) \\ &\geq \sum_j \liminf_n \mu_n((a_k, b_k)). \end{aligned} \quad (\text{Fatou})$$

So it suffices to show $\liminf_n \mu_n((a, b)) \geq \mu((a, b))$ for all $a < b$. We have $\mu_n((a, b)) = F_{\mu_n}(b-) - F_{\mu_n}(a)$. F_μ is non-decreasing, so it has at most a countable number of discontinuities. Hence there exist a', b' continuity points of F_μ with $a < a' < b' < b$. Then

$$\mu_n((a, b)) \geq F_{\mu_n}(b') - F_{\mu_n}(a') \rightarrow F_\mu(b') - F_\mu(a')$$

so $\liminf_n \mu_n((a, b)) \geq F_\mu(b') - F_\mu(a')$. By density of the continuity points, we can take $a_n \downarrow a$ and $b_n \uparrow b$ sequences of continuity points of F_μ , to conclude $\liminf_n \mu_n((a, b)) \geq F_\mu(b-) - F_\mu(a) = \mu((a, b))$. □

Definition. Let (X_n) be a sequence of random variables taking values in (M, d) , with each X_n defined on $(\Omega_n, \mathcal{F}_n, \mathbb{P}_n)$. We say that X_n *converges weakly*, or *in distribution* to a random variable X on $(\Omega, \mathcal{F}, \mathbb{P})$ if $\mu_{X_n} \Rightarrow \mu_X$ as $n \rightarrow \infty$.

Proposition.

- 1. If $X_n \xrightarrow{\mathbb{P}} X$ as $n \rightarrow \infty$ then $X_n \Rightarrow X$;
- 2. If $X_n \Rightarrow c$ for c constant, then $X_n \xrightarrow{\mathbb{P}} c$.

Example (CLT). Let (X_n) be iid, $\mathbb{E}X_1 = m$ and $\sigma^2 = \text{Var}(X_1)$. Then defining $S_n = \sum_{i=1}^n X_i$ we have

$$\frac{S_n - nm}{\sqrt{n\sigma^2}} \Rightarrow \mathcal{N}(0, 1) \text{ as } n \rightarrow \infty.$$

Definition (Tightness). Let (M, d) be a metric space. A sequence of probability measures (μ_n) on M is called *tight* if for all $\varepsilon > 0$, there exists $K \subseteq M$ compact such that $\sup_n \mu_n(K^c) < \varepsilon$.

Remark. If the metric space M is compact, then any sequence of probability measures is tight.

Theorem (Prokhorov). Let (μ_n) be a tight sequence of probability measures. Then there exists a subsequence (n_k) and a probability measure such that $\mu_{n_k} \Rightarrow \mu$ as $k \rightarrow \infty$.

Proof. We only give a proof in the case $M = \mathbb{R}$. Let $\mathbb{Q} = (x_n)_{n \geq 1}$ be an enumeration of \mathbb{Q} . Let $F_n = F_{\mu_n}$ and note $(F_n(x_1))_{n \geq 1}$ is a sequence in $[0, 1]$ so it has a convergent subsequence $F_{n_k^{(1)}} \rightarrow F(x_1)$. Now $(F_{n_k^{(1)}}(x_2))_{n \geq 2}$ is also a sequence in $[0, 1]$ so continuing like this, there exists a subsequence $(n_k^{(j)})$ such that $F_{n_k^{(j)}}(x_j) \rightarrow F(x_j)$ for all $j \in \mathbb{N}$.

Now taking the sequence $m_k = n_k^{(k)}$ we have $F_{m_k}(x) \rightarrow F(x)$ for all $x \in \mathbb{Q}$. Each F_{m_k} is non-decreasing, so F is non-decreasing as well. Define $F(x) = \lim_{q \downarrow x, q \in \mathbb{Q}} F(q)$ so F is right-continuous and non-decreasing, so F has left limits and is càdlàg.

Let x be a continuity point of F . We need to show $F_{m_k}(x) \rightarrow F(x)$. Then there exist $s_1 < x < s_2$ with $s_1, s_2 \in \mathbb{Q}$ and $|F(s_i) - F(x)| < \varepsilon/2$ for $i = 1, 2$. Hence

$$F(x) - \varepsilon < F(s_1) - \varepsilon/2 \leq F_{m_k}(s_1) \leq F_{m_k}(x) \leq F_{m_k}(s_2) \leq F(s_2) + \varepsilon/2 < F(x) + \varepsilon$$

for all k large enough, so indeed $F_{m_k}(x) \rightarrow F(x)$.

Finally we show there is a probability measure μ with $F = F_\mu$. By tightness, for all $\varepsilon > 0$ there exists N large enough so that $-N, N$ are continuity points of F and $\sup_n \mu_n([-N, N]^c) \leq \varepsilon$. Hence $F(-N) \leq \varepsilon$ and $1 - F(N) \leq \varepsilon$ so $\lim_{x \rightarrow -\infty} F(x) = 0$ and $\lim_{x \rightarrow \infty} F(x) = 1$. Define $\mu((a, b)) = F(b) - F(a)$. Then μ can be extended to the Borel σ -algebra by Caratheodory's extension theorem. \square

Definition. Let X be a random variable with values in \mathbb{R}^d . The *characteristic function* of X is defined $\phi_X(u) = \mathbb{E}[e^{i\langle u, X \rangle}]$ for $u \in \mathbb{R}^d$. We have that

- ϕ_X is continuous, $\phi_X(0) = 1$;
- ϕ_X completely determines the law of X , i.e if $\phi_X(u) = \phi_Y(u)$ for all $u \in \mathbb{R}^d$ then $\mu_X = \mu_Y$.

Lemma. Let X be a random variable in \mathbb{R}^d . Then for all $K > 0$,

$$\mathbb{P}(\|X\|_\infty \geq K) \leq C \left(\frac{K}{2}\right)^d \int_{[-K^{-1}, K^{-1}]^d} (1 - \phi_X(u)) du$$

where $C = (1 - \sin 1)^{-1}$.

Proof. Note

$$\begin{aligned} \int_{[-\lambda, \lambda]^d} \phi_X(u) du &= \int_{[-\lambda, \lambda]^d} \left(\int_{\mathbb{R}^d} \prod_{j=1}^d e^{iu_j x_j} d\mu(x) \right) du \\ &= \int_{\mathbb{R}^d} \prod_{j=1}^d \left(\int_{[-\lambda, \lambda]} e^{iu_j x_j} du_j \right) d\mu(x) \quad (\text{Fubini}) \\ &= \int_{\mathbb{R}^d} \prod_{j=1}^d \frac{e^{i\lambda x_j} - e^{-i\lambda x_j}}{ix_j} d\mu(x) \\ &= \int_{\mathbb{R}^d} \prod_{j=1}^d \frac{2 \sin(\lambda x_j)}{x_j} d\mu(x) \\ &= (2\lambda)^d \int_{\mathbb{R}^d} \prod_{j=1}^d \frac{\sin(\lambda x_j)}{\lambda x_j} d\mu(x). \end{aligned}$$

Hence,

$$\int_{[-\lambda, \lambda]^d} (1 - \phi_X(u)) du = (2\lambda)^d \int_{\mathbb{R}^d} \prod_{j=1}^d \frac{\sin(\lambda x_j)}{\lambda x_j} d\mu(x).$$

Take $f(u) = \prod_{j=1}^d \frac{\sin(u_j)}{u_j}$. We claim $|\sin(x)/x| \leq \sin(1)$ for $x \geq 1$, so if $\|u\|_\infty \geq 1$ we have $|f(u)| \leq \sin 1$. Hence

$$\mathbb{1}(\|u\|_\infty \geq 1) \leq C(1 - f(u)) \implies \mathbb{P}(\|X\|_\infty \geq K) \leq C \mathbb{E} \left[1 - f\left(\frac{X}{K}\right) \right].$$

□

Theorem (Lévy's Convergence Theorem). Let $(X_n)_{n \geq 1}, X$ be random variables with values in \mathbb{R}^d . Then $\mu_{X_n} \Rightarrow \mu_X$ if and only if $\phi_{X_n}(u) \rightarrow \phi_X(u)$ for all $u \in \mathbb{R}^d$.

We'll actually prove a stronger form:

Theorem (Lévy's Convergence Theorem). Let $(X_n)_{n \geq 1}, X$ be random variables with values in \mathbb{R}^d . Then

1. If $\mu_{X_n} \Rightarrow \mu_X$ as $n \rightarrow \infty$, then $\phi_{X_n}(\xi) \rightarrow \phi_X(\xi)$ for all $\xi \in \mathbb{R}^d$.

2. Suppose there exists $\psi : \mathbb{R}^d \rightarrow \mathbb{C}$ with $\psi(0) = 1$ and ψ is continuous at 0. Suppose $\phi_{X_n}(\xi) \rightarrow \psi(\xi)$ for all $\xi \in \mathbb{R}^d$. Then there exists a random variable X with $\psi = \phi_X$ and $\mu_{X_n} \Rightarrow \mu_X$.

Proof.

1. Trivial as $x \mapsto e^{i\langle u, x \rangle}$ is bounded and continuous.
2. First we prove that (μ_{X_n}) is tight. By the previous lemma,

$$\mathbb{P}(\|X_n\|_\infty \geq K) \leq C_d K^d \int_{[-K^{-1}, K^{-1}]^d} (1 - \phi_{X_n}(u)) du$$

where $C = 2^{-d}(1 - \sin 1)^{-1}$. Also $|1 - \phi_{X_n}(u)| \leq 2$ for all u, n so by DCT

$$K^d \int_{[-K^{-1}, K^{-1}]^d} (1 - \phi_{X_n}(u)) du \xrightarrow{n \rightarrow \infty} K^d \int_{[-K^{-1}, K^{-1}]^d} (1 - \psi(u)) du.$$

Since ψ is continuous at 0 and $\psi(0) = 1$, taking K sufficiently large we get

$$\int_{[-K^{-1}, K^{-1}]^d} (1 - \psi(u)) du < \frac{\varepsilon}{2^d C_d} (2K^{-1})^d.$$

Therefore $\mathbb{P}(\|X_n\|_\infty \geq K) \leq \varepsilon$ for n large enough. Taking K larger if necessary we have $\sup_{n \geq 0} \mathbb{P}(\|X_n\|_\infty \geq K) \leq \varepsilon$, so (μ_{X_n}) is tight. By Prokhorov's theorem, there is a subsequence (n_k) with $\mu_{X_{n_k}} \Rightarrow \mu_X$ for some random variable X . Therefore $\phi_X = \psi$.

Suppose μ_{X_n} did not converge weakly. Then there is a continuous and bounded f and a subsequence (m_k) such that $|\mathbb{E}[f(X_{m_k}) - f(X)]| > \varepsilon$ for all k . But (μ_{m_k}) is tight, so has a convergent subsequence, giving a contradiction since this limit must also be X .

□

Large Deviations

Let $(X_n)_{n \geq 1}$ be iid $\mathcal{N}(0, 1)$. Let $\hat{S}_n = \frac{1}{n} \sum_{i=1}^n X_i \sim \mathcal{N}(0, 1/n)$. Let $\delta > 0$, then

1. $\mathbb{P}(|\hat{S}_n| \geq \delta) \xrightarrow{n \rightarrow \infty} 0$.
2. $\mathbb{P}(\sqrt{n}\hat{S}_n \in A) \xrightarrow{n \rightarrow \infty} \int_A \frac{1}{\sqrt{2\pi}} e^{-x^2/2} dx$ by the CLT (even if the X_i are general centred distributions).
3. Note $\mathbb{P}(|\hat{S}_n| \geq \delta) = 1 - \int_{-\delta\sqrt{n}}^{\delta\sqrt{n}} \frac{1}{\sqrt{2\pi}} e^{-x^2/2} dx$ so $\frac{1}{n} \log \mathbb{P}(|\hat{S}_n| \geq \delta) \xrightarrow{n \rightarrow \infty} -\frac{\delta^2}{2}$.

So the “typical value” of \hat{S}_n is of order $1/\sqrt{n}$ and it can take relatively large values ($> \delta$) with very small probability ($e^{-n\delta^2/2}$). Points 1 and 2 above are universal, while 3 depends on the distribution of the X_i .

Let $(X_n)_{n \geq 1}$ be iid with $\mathbb{E}[X_1] = \bar{x}$ and $S_n = X_1 + \dots + X_n$. Let $a \in \mathbb{R}$, so

$$\mathbb{P}(S_{n+m} \geq a(n+m)) \geq \mathbb{P}(S_n \geq an)\mathbb{P}(S_m \geq am)$$

and if we define $b_n = -\log \mathbb{P}(S_n \geq an)$ we have

$$b_{n+m} \leq b_n + b_m.$$

Exercise: $\lim_{n \geq 1} \frac{b_n}{n}$ exists and $\lim_{n \geq 1} \frac{b_n}{n} = \inf_{n \geq 1} \frac{b_n}{n}$. Hence $-\frac{1}{n} \log \mathbb{P}(S_n \geq an) \xrightarrow{n \rightarrow \infty} I(a)$ for some $I(a)$. Let $M(\lambda) = \mathbb{E}[e^{\lambda X_1}]$ and $\psi(\lambda) = \log M(\lambda)$ so

$$\begin{aligned} \mathbb{P}(S_n \geq an) &= \mathbb{P}(e^{\lambda S_n} \geq e^{\lambda a n}) \leq \mathbb{E}[e^{\lambda S_n}] e^{-\lambda n a} \\ &= (\mathbb{E}[e^{\lambda X_1}])^n e^{-\lambda n a} \\ &= \exp(-n(\lambda a - \psi(\lambda))). \end{aligned}$$

Let $\psi^*(a) = \sup_{\lambda \geq 0} (\lambda a - \psi(\lambda)) \geq 0$ so

$$\mathbb{P}(S_n \geq an) \leq \exp(-n\psi^*(a)) \implies -\frac{1}{n} \log \mathbb{P}(S_n \geq an) \geq \psi^*(a).$$

Theorem (Cramer's Theorem). *Let $(X_n)_{n \geq 1}$ be an iid sequence of random variables with $\mathbb{E}X_1 = \bar{x}$. Let $S_n = \sum_{i=1}^n X_i$. Then*

$$-\frac{1}{n} \log \mathbb{P}(S_n \geq an) \xrightarrow{n \rightarrow \infty} \psi^*(a) \quad \forall a \geq \bar{x}$$

where $\psi^*(a) = \sup_{\lambda \geq 0} (\lambda a - \psi(\lambda))$ and $\psi(\lambda) = \log \mathbb{E}[e^{\lambda X_1}]$.

First we prove a preliminary lemma.

Lemma. *Let $M(\lambda) = \mathbb{E}[e^{\lambda X_1}]$ and $\psi(\lambda) = \log \mathbb{E}[e^{\lambda X_1}]$. Then the functions M and ψ are continuous in $D = \{\lambda : M(\lambda) < \infty\}$, and differentiable in $\text{int}(D)$ with*

$$M'(\lambda) = \mathbb{E}[X_1 e^{\lambda X_1}] \text{ and } \psi'(\lambda) = \frac{M'(\lambda)}{M(\lambda)} \quad \forall \lambda \in \text{int}(D).$$

Proof. Continuity follows by dominated convergence. For the derivative we have

$$\frac{M(\nu + \varepsilon) - M(\nu)}{\varepsilon} = \mathbb{E} \left[\frac{e^{(\nu + \varepsilon)X_1} - e^{\nu X_1}}{\varepsilon} \right]$$

and

$$\left| \frac{e^{(\nu + \varepsilon)X_1} - e^{\nu X_1}}{\varepsilon} \right| \leq e^{\nu X_1} \left| \frac{e^{\varepsilon X_1} - 1}{\varepsilon} \right|.$$

Let $\delta > 0$ be sufficiently small so that $\nu + \delta \in \text{int}(D)$. Take $\varepsilon \in (-\delta, \delta)$. Then

$$\left| \frac{e^{\varepsilon X_1} - 1}{\varepsilon} \right| \leq \frac{e^{\delta |X_1|} - 1}{\delta}$$

so

$$\left| \frac{e^{(\nu + \varepsilon)X_1} - e^{\nu X_1}}{\varepsilon} \right| \leq e^{\nu X_1} \frac{e^{\delta |X_1|} - 1}{\delta}$$

and apply dominated convergence. □

Now we are ready to prove Cramer:

Proof of Cramer's Theorem. By a Chernoff bound we have

$$\liminf_{n \rightarrow \infty} -\frac{1}{n} \log \mathbb{P}(S_n \geq an) \geq \psi^*(a)$$

so we need to show

$$\limsup_{n \rightarrow \infty} -\frac{1}{n} \log \mathbb{P}(S_n \geq an) \leq \psi^*(a).$$

Replace each X_i with $\tilde{X}_i = X_i - a$ and write $\tilde{S}_n = \sum_{i=1}^n \tilde{X}_i$, $\tilde{M}(\lambda) = \mathbb{E}[e^{\lambda \tilde{X}_1}] = e^{-a\lambda} M(\lambda)$, $\tilde{\psi}(\lambda) = \psi(\lambda) - a\lambda$. Then we want to show

$$\begin{aligned} \limsup_{n \rightarrow \infty} -\frac{1}{n} \log \mathbb{P}(S_n \geq an) &= \limsup_{n \rightarrow \infty} -\frac{1}{n} \log \mathbb{P}(\tilde{S}_n \geq 0) \\ &\leq \tilde{\psi}^*(0) \end{aligned}$$

where $\tilde{\psi}^*(0) = \sup_{\lambda \geq 0} (-\tilde{\psi}(\lambda))$. So it suffices to show

$$\liminf_{n \rightarrow \infty} \frac{1}{n} \mathbb{P}(S_n \geq 0) \geq \inf_{\lambda \geq 0} \psi(\lambda)$$

whenever $\bar{x} \leq 0$. Write $\mu = \mu_{X_1}$ and assume that $M(\lambda) < \infty$ for all $\lambda \geq 0$. Define a new measure for all $\theta \geq 0$ by

$$\frac{d\mu_\theta}{d\mu}(x) = \frac{e^{\theta x}}{M(\theta)}$$

so

$$\mathbb{E}_\theta[f(X_1)] = \int_{\mathbb{R}} \frac{e^{\theta x} f(x)}{M(\theta)} d\mu(x).$$

Then if $X_1, \dots, X_n \sim \mu$ are iid we have

$$\mathbb{E}_\theta[F(X_1, \dots, X_n)] = \int_{\mathbb{R}^n} F(x_1, \dots, x_n) \prod_{i=1}^n \frac{e^{\theta x_i}}{M(\theta)} d\mu(x_i).$$

Set $g(\theta) = \mathbb{E}_\theta[X_1] = \int_{\mathbb{R}} \frac{e^{\theta x} x}{M(\theta)} d\mu(x) = \frac{M'(\theta)}{M(\theta)} = \psi'(\theta)$. We find θ such that $g(\theta) = 0$. Suppose $\mu((0, \infty)) = \mathbb{P}(X_1 > 0) > 0$. Then

$$\psi(\theta) = \log \mathbb{E}[e^{\theta X_1}] \implies \lim_{\theta \rightarrow \infty} \psi(\theta) = \infty$$

so there exists $\eta \geq 0$ such that $\psi(\eta) = \inf_{\lambda \geq 0} \psi(\lambda)$ and $\psi'(\eta) = 0$, i.e $g(\eta) = 0$. We have

$$\begin{aligned} \mathbb{P}(S_n \geq 0) &\geq \mathbb{P}(S_n \in [0, \varepsilon n]) \geq \mathbb{E}[e^{\eta S_n - \eta \varepsilon n} \mathbb{1}(S_n \in [0, \varepsilon n])] \\ &= e^{-\eta \varepsilon n} (M(\eta))^n \underbrace{\mathbb{P}_\eta(S_n \in [0, \varepsilon n])}_{\rightarrow \frac{1}{2} \text{ by CLT}} \end{aligned}$$

using the fact $\mathbb{E}_\eta[X_1] = 0$. Hence

$$\frac{1}{n} \log \mathbb{P}(S_n \geq 0) \geq -\eta \varepsilon + \log M(\eta) + \frac{\log \mathbb{P}_\eta(S_n \in [0, \varepsilon n])}{n}$$

so taking limits

$$\liminf_{n \rightarrow \infty} \log \mathbb{P}(S_n \geq 0) \geq \log M(\eta) - \eta \varepsilon \geq \inf_{\lambda \geq 0} \psi(\lambda) - \eta \varepsilon$$

so take $\varepsilon \rightarrow 0$. If $\mathbb{P}(X_1 > 0) = 0$, then

$$\mathbb{P}(S_n \geq 0) = (\mu(0))^n \implies \frac{1}{n} \log \mathbb{P}(S_n \geq 0) = \log \mu(0) \geq \inf_{\lambda \geq 0} \psi(\lambda)$$

since $\inf_{\lambda \geq 0} \psi(\lambda) \leq \lim_{\lambda \rightarrow \infty} \psi(\lambda) = \log \mu(0)$.

In the general case (not assuming $M(\lambda) < \infty$ for all $\lambda \geq 0$): let $K > 0$ and define $\nu = \mu_{X_1 | |X_1| \leq K}$, $\nu_n = \mu_{S_n | \cap_{i=1}^n \{|X_i| \leq K\}}$, $\mu = \mu_{X_1}$ and $\mu_n = \mu_{S_n}$. Then

$$\mu_n([0, \infty)) \geq \nu_n([0, \infty))(\mu([-K, K]))^n$$

and

$$\frac{1}{n} \log \mu_n([0, \infty)) \geq \frac{\log \nu_n([0, \infty))}{n} + \mu([-K, K]).$$

Define $\psi_K(\lambda) = \log \int_{-K}^K e^{\lambda x} d\mu(x)$ so

$$\log \int_{-\infty}^{\infty} e^{\lambda x} d\nu(x) = \psi_K(\lambda) - \log \mu([-K, K])$$

therefore

$$\begin{aligned} \frac{1}{n} \log \mu_n([0, \infty)) &\geq \frac{\log \nu_n([0, \infty))}{n} + \mu([-K, K]) \\ &\geq \inf_{\lambda \geq 0} \left(\log \int_{-\infty}^{\infty} e^{\lambda x} d\nu(x) \right) + \log \mu([-K, K]) \\ &= \inf_{\lambda \geq 0} \psi_K(\lambda) := J_K. \end{aligned}$$

Then $J_K \uparrow J$ as $k \rightarrow \infty$ for some J . There exists K large so that $J_K > -\infty$, so take K larger and so that $\mu((0, K)) > 0$. Then $J_K = \inf_{\lambda \geq 0} \psi_K(\lambda)$, which implies $J > -\infty$. Note $\{\lambda : \psi_K(\lambda) \leq T\}$ are compact (by continuity of ψ_K) nested subsets so there exists $\lambda_0 \in \bigcap_{K \in \mathbb{N}} \{\lambda : \psi_K(\lambda) \leq T\}$, so $\psi(\lambda_0) = \lim_K \psi_K(\lambda_0) \leq J$. \square

Brownian Motion

Definition. $(B_t)_{t \geq 0}$ is called a *Brownian motion* in \mathbb{R}^d started from $x \in \mathbb{R}^d$ if (B_t) is a continuous process and

- (i) $B_0 = x$ almost-surely;
- (ii) For all $s < t$, $B_t - B_s \sim \mathcal{N}(0, (t-s)I_d)$;
- (iii) (B_t) has independent increments, independent of B_0 .

If $x_0 = 0$ we call (B_t) the *standard Brownian motion*.

Note. (ii) & (iii) uniquely characterise the law of (B_t) .

Example. Let (B_t) be a standard Brownian motion in \mathbb{R} and $U \sim \text{Unif}([0, 1])$. Define

$$\tilde{B}_t = \begin{cases} B_t & t \neq U \\ 0 & t = U \end{cases}.$$

Then \tilde{B} is almost-surely discontinuous, so even though it has the same finite dimensional distribution, it is not a Brownian motion.

Theorem (Weiner). *There exists a Brownian motion on some probability space.*

Proof.

1. We first construct a Brownian motion in $d = 1$. We first construct in $[0, 1]$, i.e. $(B_t)_{t \in [0, 1]}$ for $d = 1$. Let $\mathcal{D}_0 = \{0, 1\}$, $\mathcal{D}_n = \{k2^{-n} : 0 \leq k \leq 2^n\}$ and $\mathcal{D} = \bigcup_{n \geq 0} \mathcal{D}_n$. We construct $(B_d)_{d \in \mathcal{D}}$ inductively. Let $(Z_d)_{d \in \mathcal{D}}$ be iid $\mathcal{N}(0, 1)$ on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$. For $\mathcal{D}_0 = \{0, 1\}$ let $B_0 = 0$ and $B_1 = Z_1$. Now suppose we've constructed $(B_d)_{d \in \mathcal{D}_{n-1}}$ satisfying (ii) & (iii). For $d \in \mathcal{D}_n \setminus \mathcal{D}_{n-1}$ let $d_- = d - 2^{-n}$, $d_+ = d + 2^{-n} \in \mathcal{D}_{n-1}$. Then set

$$B_d = \frac{B_{d_-} + B_{d_+}}{2} + \frac{Z_d}{2^{\frac{n+1}{2}}}$$

so

$$\begin{aligned} B_d - B_{d_-} &= \frac{B_{d_+} - B_{d_-}}{2} + \frac{Z_d}{2^{\frac{n+1}{2}}} \\ B_{d_+} - B_d &= \underbrace{\frac{B_{d_+} - B_{d_-}}{2}}_{:= N_d} - \underbrace{\frac{Z_d}{2^{\frac{n+1}{2}}}}_{:= N'_d}. \end{aligned}$$

So by induction $N_d \sim \mathcal{N}\left(0, \frac{d_+ - d_-}{4}\right) = \mathcal{N}(0, 2^{-n-1})$ and $N'_d \sim \mathcal{N}(0, 2^{-n-1})$.

Also by induction N_d and N'_d are independent, so $B_d - B_{d_-}$ and $B_{d_+} - B_d$

are Gaussian. To prove they are independent, we show $\text{Cov}(N_d + N'_d, N_d - N'_d) = 0$. Indeed

$$\text{Cov}(N_d + N'_d, N_d - N'_d) = \text{Var}(N_d) - \text{Var}(N'_d) = 0.$$

So we have checked $(B_d - B_{d-2^{-n}})_{d \in \mathcal{D}_n}$ are independent for consecutive intervals. If not consecutive, then express each increment as half the increment of the previous scale plus an independent Gaussian. We have so far constructed $(B_d)_{d \in \mathcal{D}}$ satisfying the assumptions. Note that for $d, q \in \mathcal{D}$, $p > 0$

$$\mathbb{E}[|B_d - B_q|^p] = |d - q|^{p/2} \mathbb{E}[|N|^p], \text{ where } Z \sim \mathcal{N}(0, 1).$$

And for all $p > 0$, $\mathbb{E}|N|^p < \infty$. So by Kolmogorov's continuity criterion, we have that $(B_d)_{d \in \mathcal{D}}$ is almost-surely α -Hölder continuous for all $\alpha < 1/2$. So we can extend to all of $[0, 1]$. Set $B_t = \lim_{i \rightarrow \infty} B_{d_i}$, $d_i \in \mathcal{D}$, $d_i \rightarrow t$. It is immediate that $(B_t)_{t \in [0, 1]}$ is almost-surely α -Hölder continuous for all $\alpha < 1/2$.

We need to check (ii) and (iii). Let $0 = t_0 \leq t_1 \leq \dots \leq t_k \leq 1$. Then $(B_{t_i} - B_{t_{i-1}})_{i=1, \dots, k}$ are independent Gaussians with variance $t_i - t_{i-1}$. Let $0 \leq t_0^n \leq t_1^n \leq \dots \leq t_k^n$ be dyadic rationals with $t_0^n \rightarrow t_0, \dots, t_k^n \rightarrow t_k$. Then by continuity

$$B_{t_j^n} - B_{t_{j-1}^n} \xrightarrow{n \rightarrow \infty} B_{t_j} - B_{t_{j-1}} \quad (*)$$

for all j almost-surely. Hence

$$\begin{aligned} \mathbb{E} \left[\exp \left(i \sum_{j=1}^k u_j (B_{t_j^n} - B_{t_{j-1}^n}) \right) \right] &= \prod_{j=1}^k \exp \left(-\frac{u_j^2 (t_j^n - t_{j-1}^n)}{2} \right) \\ &\xrightarrow{n \rightarrow \infty} \prod_{j=1}^k \exp \left(-\frac{u_j^2 (t_j - t_{j-1})}{2} \right). \end{aligned}$$

So by Levy's convergence theorem, since the limit is the characteristic function of independent $\mathcal{N}(0, t_j - t_{j-1})$ and since we have (*), this forces the law of $(B_{t_j} - B_{t_{j-1}})_{j=1}^k$ to be independent $\mathcal{N}(0, t_j - t_{j-1})$. Hence $(B_t)_{t \in [0, 1]}$ satisfies all the desired properties.

2. Take $\{(B_t^i)_{t \in [0, 1]}\}_{i \in \mathbb{N}}$ to be independent Brownian motions. Then define $B_t = B_{t - \lfloor t \rfloor}^{[t]} + \sum_{i=0}^{\lfloor t \rfloor - 1} B_1^i$.
3. For general d , let $(B_t^1)_{t \geq 0}, \dots, (B_t^d)_{t \geq 0}$ be independent 1-dimensional Brownian motions and set $B_t = (B_t^1, \dots, B_t^d)$ and check this works.

□

Theorem. *Let B be a standard Brownian motion in \mathbb{R}^d . Then*

- (a) If U is an orthogonal matrix, then $UB = (UB_t)_{t \geq 0}$ is also a standard Brownian motion. In particular, $-B$ is a standard Brownian motion.*
- (b) For all $\lambda > 0$, $\left(\frac{B_{\lambda t}}{\sqrt{\lambda}}\right)_{t \geq 0}$ is also a standard Brownian motion.*
- (c) For all $s \geq 0$, $(B_{t+s} - B_s)_{t \geq 0}$ is also a standard Brownian motion, and it is independent of \mathcal{F}_s^B where $\mathcal{F}_s^B = \sigma(B_u : u \leq s)$ (simple Markov property).*

Proof. Follows from definition of Brownian motion. □

Properties of Brownian motion

Proposition (Time inversion). Let B be a standard Brownian motion in one-dimension. Let

$$X_t = \begin{cases} tB_{1/t} & t > 0 \\ 0 & t = 0 \end{cases}.$$

Then $(X_t)_{t \geq 0}$ is a standard Brownian motion.

Proof. Let $t_1, \dots, t_k > 0$. Then $(B_{t_1}, \dots, B_{t_k})$ is a Gaussian random vector with zero mean and $\text{Cov}(B_s, B_t) = s \wedge t$.

Need to check $(X_{t_1}, \dots, X_{t_k})$ is Gaussian with zero mean and covariance as above. The vector is certainly Gaussian with zero mean. Furthermore

$$\text{Cov}(X_{t_i}, X_{t_j}) = \text{Cov}(t_i B_{1/t_i}, t_j B_{1/t_j}) = t_i t_j \text{Cov}(B_{1/t_i}, B_{1/t_j}) = t_i \wedge t_j.$$

Finally we show X is continuous. For $t > 0$ X is clearly continuous since B is. So it suffices to show $X_t \xrightarrow{t \rightarrow 0} 0$ almost-surely. Note $(X_t)_{t \in \mathbb{Q}_+} =^d (B_t)_{t \in \mathbb{Q}_+}$ since X, B have the same finite dimensional distribution. Hence $\lim_{\substack{t \downarrow 0 \\ t \in \mathbb{Q}_+}} X_t = \lim_{\substack{t \downarrow 0 \\ t \in \mathbb{Q}_+}} B_t = 0$ almost-surely. Since \mathbb{Q}_+ is dense and X is continuous for $t > 0$ we conclude

$$\lim_{t \rightarrow 0} X_t = \lim_{t \rightarrow 0} B_t = 0$$

almost-surely. □

Corollary. Let B be a standard Brownian motion in one-dimension. Then $\frac{B_t}{t} \xrightarrow{t \rightarrow \infty} 0$ almost-surely.

Proof. We have $\lim_{t \rightarrow \infty} \frac{B_t}{t} = \lim_{t \rightarrow 0} t B_{1/t} = 0$ almost-surely by the previous. □

Definition. For $s \geq 0$ let $\mathcal{F}_s^+ = \bigcap_{t > s} \mathcal{F}_t^B$ (where $\mathcal{F}_t^B = \sigma(B_u : u \leq t)$ as before).

Theorem. For all $s \geq 0$, $(B_{t+s} - B_s)_{t \geq 0}$ is independent of \mathcal{F}_s^+ .

Proof. We need to show that if $t_1, \dots, t_k \in \mathbb{R}_+$ and F is continuous and bounded on $(\mathbb{R}^d)^k$ for any $A \in \mathcal{F}_s^+$ we have

$$\begin{aligned} & \mathbb{E}[F(B_{t_1+s} - B_s, \dots, B_{t_k+s} - B_s) \mathbb{1}(A)] \\ &= \mathbb{E}[F(B_{t_1+s} - B_s, \dots, B_{t_k+s} - B_s)] \mathbb{P}(A). \end{aligned}$$

Indeed, if $s_n \downarrow s$ is strictly decreasing, by continuity we have

$$B_{t_1+s_n} - B_{s_n} \rightarrow B_{t_1+s} - B_s \text{ as } n \rightarrow \infty \text{ almost-surely.}$$

Hence

$$\begin{aligned} & \mathbb{E}[F(B_{t_1+s} - B_s, \dots, B_{t_k+s} - B_s) \mathbb{1}(A)] \\ &= \lim_{n \rightarrow \infty} \mathbb{E}[F(B_{t_1+s_n} - B_{s_n}, \dots, B_{t_k+s_n} - B_{s_n}) \mathbb{1}(A)] \end{aligned}$$

by dominated convergence. Since $A \in \mathcal{F}_s^+$, we have $A \in \mathcal{F}_{s_n}^B$ for all n . Hence by the simple Markov property

$$\begin{aligned} & \lim_{n \rightarrow \infty} \mathbb{E}[F(B_{t_1+s_n} - B_{s_n}, \dots, B_{t_k+s_n} - B_{s_n}) \mathbb{1}(A)] \\ &= \lim_{n \rightarrow \infty} \mathbb{E}[F(B_{t_1+s_n} - B_{s_n}, \dots, B_{t_k+s_n} - B_{s_n})] \mathbb{P}(A) \\ &= \mathbb{E}[F(B_{t_1+s} - B_s, \dots, B_{t_k+s} - B_s)] \mathbb{P}(A) \end{aligned}$$

by dominated convergence. \square

Corollary (Blumenthal's 0-1 law). *The σ -algebra \mathcal{F}_0^+ is trivial, i.e if $A \in \mathcal{F}_0^+$ then $\mathbb{P}(A) \in \{0, 1\}$.*

Proof. If $A \in \mathcal{F}_0^+$ then $A \in \sigma(B_t : t \geq 0)$. But $\sigma(B_t : t \geq 0)$ is independent of \mathcal{F}_0^+ by the previous, so A is independent of itself and $\mathbb{P}(A) = \mathbb{P}(A \cap A) = \mathbb{P}(A)^2$. \square

Theorem. *Let B be a standard Brownian motion in one-dimension. Then define $\tau = \inf\{t > 0 : B_t > 0\}$ and $\sigma = \inf\{t > 0 : B_t = 0\}$. Then $\mathbb{P}(\tau = 0) = \mathbb{P}(\sigma = 0) = 1$.*

Proof. Note

$$\{\tau = 0\} = \bigcap_{k \geq n} \underbrace{\{\exists 0 < \varepsilon < 1/k \text{ s.t. } B_\varepsilon > 0\}}_{\in \mathcal{F}_{1/n}^B}$$

for all n , so $\{\tau = 0\} \in \mathcal{F}_0^+$. So $\mathbb{P}(\tau = 0) \in \{0, 1\}$ and it is enough to show $\mathbb{P}(\tau = 0) > 0$. For $t > 0$ we have $\mathbb{P}(\tau \leq t) \geq \mathbb{P}(B_t > 0) = 1/2$ so taking the limit $t \downarrow 0$ we have $\mathbb{P}(\tau = 0) \geq 1/2$ and so $\mathbb{P}(\tau = 0) = 1$.

Also note $\inf\{t > 0 : B_t < 0\} = 0$ almost-surely since $-B_t$ is also a standard Brownian motion. Since B is continuous, this means $\inf\{t > 0 : B_t = 0\} = 0$ almost-surely by the intermediate value theorem. \square

Proposition. Let B be a standard Brownian motion in one dimension. Let $S_t = \sup_{s \leq t} B_s, I_t = \inf_{s \leq t} B_s$. Then

1. For all $\varepsilon > 0$, $S_\varepsilon > 0$ and $I_\varepsilon < 0$ almost-surely;
2. $\sup_{t \geq 0} B_t = \infty$ almost-surely and $\inf_{t \geq 0} B_t = -\infty$ almost-surely.

Proof.

1. Let $t_n \downarrow 0$ as $n \rightarrow \infty$. Then $\{S_\varepsilon > 0\} \supseteq \{B_{t_n} > 0 \text{ i.o.}\} \in \mathcal{F}_0^+$. Hence $\mathbb{P}(B_{t_n} > 0 \text{ i.o.}) = \mathbb{P}(\limsup\{B_{t_n} > 0\}) \geq \limsup \mathbb{P}(B_{t_n} > 0) = 1/2$ by Fatou. Hence by Blumenthal's 0-1 law $\mathbb{P}(S_\varepsilon > 0) = 1$.

2. Note $\sup_{t \geq 0} B_t = \sup_{t \geq 0} B_{\lambda t} \stackrel{d}{=} \sqrt{\lambda} \sup_{t \geq 0} B_t$ for any $\lambda > 0$. So $S_\infty \stackrel{d}{=} \alpha S_\infty$ for any $\alpha > 0$. Hence $\mathbb{P}(S_\infty \geq x) = \mathbb{P}(S_\infty \geq 0) = 1$ for all x and so $\mathbb{P}(S_\infty = \infty) = 1$.

□

Remark. (1) also follows immediately from the preceding proposition.

Proposition. Let B be a standard Brownian motion in \mathbb{R}^d and let C be a cone with origin at 0 and non-empty interior, i.e $C = \{tu : t > 0, u \in A\}$ with $A \subseteq \mathbb{S}^1$ (unit sphere in \mathbb{R}^d). Let $H_C = \inf\{t > 0 : B_t \in C\}$. Then $\mathbb{P}(H_C = 0) = 1$.

Proof. We have $\{H_C = 0\} \in \mathcal{F}_0^+$. Also $\mathbb{P}(B_t \in C) = \mathbb{P}(B_1 \in C)$ by scale invariance of the Brownian motion and C . Also $\mathbb{P}(B_1 \in C) > 0$ since $\text{int}(C) \neq \emptyset$. Hence $\mathbb{P}(H_C \leq t) \geq \mathbb{P}(B_t \in C) > 0$. □

Theorem (Strong Markov property). *Let B be a standard Brownian motion and let T be an almost-surely finite stopping time. Then $(B_{t+T} - B_T)_{t \geq 0}$ is a standard Brownian motion, and it is independent of \mathcal{F}_T^+ .*

Proof. Let $T_n = 2^{-n} \lceil 2^n T \rceil$ so $T_n \downarrow T$. For $k \in \mathbb{N}$, let $B_t^{(k)} = B_{t+k2^{-n}} - B_{k2^{-n}}$ and let $B_*(t) = B_{t+T_n} - B_{T_n}$. We will show B_* is a Brownian motion independent of $\mathcal{F}_{T_n}^+$.

B_* is certainly continuous. Let A be any set, $E \in \mathcal{F}_{T_n}^+$. Then

$$\begin{aligned} \mathbb{P}(B_* \in A, E) &= \sum_{k \in \mathbb{N}} \mathbb{P}(T_n = k2^{-n}, B^{(k)} \in A, E) \\ &= \sum_{k \in \mathbb{N}} \mathbb{P}(T_n = k2^{-n}, E) \mathbb{P}(B^{(k)} \in A) \\ &= \sum_{k \in \mathbb{N}} \mathbb{P}(E) \mathbb{P}(B \in A) \end{aligned}$$

since $\{T_n = k2^{-n}\} \cap E \in \mathcal{F}_{k2^{-n}}^+$ and $B^{(k)}$ is a Brownian motion independent of $\mathcal{F}_{k2^{-n}}^+$. Hence $B_* =^d B$ and B_* is independent of $\mathcal{F}_{T_n}^+$.

Now note

$$B_{t+s+T} - B_{s+T} = \lim_{n \rightarrow \infty} \underbrace{(B_{s+t+T_n} - B_{s+T_n})}_{\mathcal{N}(0,t)} \text{ almost-surely.}$$

Hence $(B_{t+T} - B_T)_{t \geq 0}$ is a standard Brownian motion. We need to show it is independent of \mathcal{F}_T^+ . Let $t_1, \dots, t_k \geq 0$ and $F : (\mathbb{R}^d)^k \rightarrow \mathbb{R}$ be a continuous and bounded function. Let $A \in \mathcal{F}_T^+$. Then

$$\begin{aligned} &\mathbb{E}[F(B_{t_1+T} - B_T, \dots, B_{t_k+T} - B_T) \mathbb{1}(A)] \\ &= \lim_{n \rightarrow \infty} \mathbb{E}[F(B_{t_1+T_n} - B_{T_n}, \dots, B_{t_k+T_n} - B_{T_n}) \mathbb{1}(A)] \end{aligned}$$

by dominated convergence. Since $A \in \mathcal{F}_T^+$, $A \in \mathcal{F}_{T_n}^+$ so using the fact B_* is independent of $\mathcal{F}_{T_n}^+$ concludes the proof. \square

Theorem (Reflection principle). *Let B be a standard Brownian motion in dimension 1 and let T be an almost-surely finite stopping time. Define*

$$\tilde{B}_t = \begin{cases} B_t & 0 \leq t \leq T \\ 2B_T - B_t & t > T \end{cases}.$$

Then \tilde{B} is a standard Brownian motion.

Proof. We know $B_t^{(T)} := (B_{t+T} - B_T)_{t \geq 0}$ is a standard Brownian motion, independent of \mathcal{F}_T^+ , so in particular it's independent of $(B_t)_{0 \leq t \leq T}$. Then $-B^{(T)}$ is also a standard Brownian motion, independent of \mathcal{F}_T^+ . Hence

$$((B_t)_{0 \leq t \leq T}, B^{(T)}) =^d ((B_t)_{0 \leq t \leq T}, -B^{(T)}).$$

Define the concatenation operation ψ_T by $\psi_T(X, Y)(t) = X_T \mathbb{1}(t \leq T) + (X_T + Y_{t-T}) \mathbb{1}(t > T)$. Since T is a stopping time, $\psi_T : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ is measurable with respect to the product σ -algebra $\mathcal{A} \otimes \mathcal{A}$ on $\mathcal{C} \times \mathcal{C}$ and \mathcal{A} on \mathcal{C} .

We have $\psi_T(B, B^{(T)}) = B$, while $\psi_T(B, -B^{(T)}) = \tilde{B}$. Since ψ_T is measurable, and the two pairs have the same law we conclude $B \stackrel{d}{=} \tilde{B}$. \square

Corollary. Let $S_t = \sup_{s \leq t} B_s$. Let $b > 0$ and $a \leq b$. Then

$$\mathbb{P}(S_t \geq b, B_t \leq a) = \mathbb{P}(B_t \geq 2b - a).$$

Proof. For $x > 0$ write $T_x = \inf\{t \geq 0 : B_t = x\}$. We have $S_\infty = \infty$ almost-surely so $T_x < \infty$ almost-surely. Also $B_{T_x} = x$ by continuity. Note

$$\{S_t \geq b\} = \{T_b \leq t\}$$

so by taking (\tilde{B}_t) as before with stopping time $T = T_b$,

$$\begin{aligned} \mathbb{P}(S_t \geq b, B_t \leq a) &= \mathbb{P}(T_b \leq t, B_t \leq a) \\ &= \mathbb{P}(\tilde{B}_t \geq 2b - a, T_b \leq t) \\ &= \mathbb{P}(\tilde{B}_t \geq b + (b - a), T_b \leq t) \\ &= \mathbb{P}(B_t \geq 2b - a). \end{aligned}$$

\square

Corollary. $S_t \stackrel{d}{=} |B_t|$.

Proof.

$$\begin{aligned} \mathbb{P}(S_t \geq a) &= \mathbb{P}(S_t \geq a, B_t \geq a) + \underbrace{\mathbb{P}(S_t \geq a, B_t \leq a)}_{\mathbb{P}(B_t \geq a)} \\ &= 2\mathbb{P}(B_t \geq a) \\ &= \mathbb{P}(|B_t| \geq a). \end{aligned}$$

\square

Corollary. For $x > 0$ let $T_x = \inf\{t \geq 0 : B_t = x\}$. Then $T_x \stackrel{d}{=} \left(\frac{x}{B_1}\right)^2$.

Martingales for Brownian motion

Theorem. Let $(B_t)_{t \geq 0}$ be a standard Brownian motion in dimension 1.

1. $(B_t)_{t \geq 0}$ is a martingale;
2. $(B_t^2 - t)$ is a martingale.

Proof. Let $s \leq t$. Then

$$\begin{aligned}\mathbb{E}[B_t | \mathcal{F}_s^+] &= \mathbb{E}[B_t - B_s + B_s | \mathcal{F}_s^+] \\ &= B_s \text{ almost-surely.}\end{aligned}$$

Also

$$\begin{aligned}\mathbb{E}[B_t^2 - t | \mathcal{F}_s^+] &= \mathbb{E}[(B_t - B_s)^2 | \mathcal{F}_s^+] + 2\mathbb{E}[(B_t - B_s)B_s | \mathcal{F}_s^+] + \mathbb{E}[B_s^2 | \mathcal{F}_s^+] - t \\ &= t - s + B_s^2 - t \\ &= B_s^2 - s.\end{aligned}$$

□

Corollary. Let B be a standard Brownian motion in dimension 1 and let $x, y > 0$. Then

$$\mathbb{P}(T_{-x} < T_y) = \frac{y}{x+y}$$

and $\mathbb{E}[T_{-x} \wedge T_y] = xy$.

Proof. Follows from optional stopping theorem and martingales from before. □

Proposition. Let B be a standard Brownian motion in \mathbb{R}^d . Then for any $u \in \mathbb{R}^d$

$$M_t = \exp\left(\langle u, B_t \rangle - \frac{|u|^2 t}{2}\right)$$

is an (\mathcal{F}_t^+) -martingale.

Proof. We have

$$\begin{aligned}\mathbb{E}[M_t | \mathcal{F}_s^+] &= \mathbb{E}[\exp(\langle u, B_t - B_s \rangle + \langle u, B_s \rangle) | \mathcal{F}_s^+] e^{-\frac{|u|^2 t}{2}} \\ &= \exp(\langle u, B_s \rangle) \exp\left(\frac{|u|^2(t-s)}{2}\right) e^{-\frac{|u|^2 t}{2}} \\ &= M_s.\end{aligned}$$

□

Let (S_n) be a SSRW on \mathbb{Z} and let f be a function. Then

$$\mathbb{E}[f(S_{n+1}) | S_0, \dots, S_n] = \frac{f(S_n + 1) + f(S_n - 1)}{2}$$

so

$$\mathbb{E}[f(S_{n+1}) - f(S_n) | S_0, \dots, S_n] = \frac{1}{2} (f(S_n + 1) - 2f(S_n) + f(S_n - 1)).$$

Setting $\tilde{\Delta}f(x) = f(x+1) - 2f(x) + f(x-1)$ we have that $\left(f(S_n) - \frac{1}{2} \sum_{k=0}^{n-1} \tilde{\Delta}f(S_k)\right)$ is a martingale.

Theorem. Let $f(t, x) : \mathbb{R}_+ \times \mathbb{R}^d \rightarrow \mathbb{R}$ be continuously differentiable in t and twice continuously differentiable in x . Assume f and all its derivatives up to second order are bounded. Then the process

$$M_t = f(t, B_t) - B(0, B_0) - \int_0^t \left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r, B_r) dr$$

is an \mathcal{F}_t^+ -martingale.

Proof. M is certainly adapted and is integrable by boundedness. Let $t, s > 0$ so

$$\begin{aligned} M_{t+s} - M_s &= f(t+s, B_{t+s}) - f(s, B_s) - \int_s^{t+s} \left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r, B_r) dr \\ &= f(t+s, B_{t+s}) - f(s, B_s) - \int_0^t \left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r+s, B_{r+s}) dr. \end{aligned}$$

Hence

$$\begin{aligned} \mathbb{E}[M_{t+s} - M_s | \mathcal{F}_s^+] &= -f(s, B_s) + \mathbb{E}[f(t+s, B_{t+s} - B_s + B_s) | \mathcal{F}_s^+] \\ &\quad - \int_0^t \mathbb{E} \left[\left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r, B_r) dr | \mathcal{F}_s^+ \right] dr. \end{aligned}$$

(Fubini and def of cond expectation)

Since $B_{t+s} - B_s$ is independent of \mathcal{F}_s^+ and B_s ,

$$\mathbb{E}[f(t+s, B_{t+s} - B_s + B_s) | \mathcal{F}_s^+] = \int_{\mathbb{R}^d} f(t+s, x + B_s) p_t(0, x) dx$$

where $p_t(0, x) = (2\pi t)^{-1/2} \exp\left(-\frac{|x|^2}{2t}\right)$. Similarly

$$\mathbb{E} \left[\left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r, B_r) dr | \mathcal{F}_s^+ \right] = \int_{\mathbb{R}^d} \left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r+s, B_s + x) p_r(0, x) dx$$

and furthermore

$$\begin{aligned} &\int_0^t \int_{\mathbb{R}^d} \left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r+s, B_s + x) p_r(0, x) dx \\ &= \lim_{\varepsilon \downarrow 0} \underbrace{\int_\varepsilon^t \int_{\mathbb{R}^d} \left(\frac{\partial}{\partial r} + \frac{1}{2} \Delta \right) f(r+s, B_s + x) p_r(0, x) dx dr}_{:= A(\varepsilon)}. \end{aligned} \quad (\text{DCT})$$

Integration by parts gives

$$\begin{aligned} A(\varepsilon) &= \int_{\mathbb{R}^d} (f(s+t, B_s + x) p_t(0, x) - f(\varepsilon+s, B_s + x) p_\varepsilon(0, x)) dx \\ &\quad - \int_\varepsilon^t \int_{\mathbb{R}^d} f(r+s, B_s + x) \frac{\partial}{\partial r} p_r(0, x) dx dr \\ &\quad + \int_\varepsilon^t \int_{\mathbb{R}^d} f(r+s) \frac{1}{2} \Delta p_r(0, x) dx dr. \end{aligned}$$

Since $\frac{\partial}{\partial r} p_r = \frac{1}{2} \Delta p_r$ this means

$$A(\varepsilon) = \int_{\mathbb{R}^d} (f(s+t, B_s+x) p_t(0, x) - f(\varepsilon+s, B_s+x) p_\varepsilon(0, x)) dx.$$

Thus

$$\begin{aligned} & \mathbb{E}[M_{t+s} - M_s | \mathcal{F}_s^+] \\ &= \int_{\mathbb{R}^d} f(t+s, x+B_s) p_t(0, x) dx - f(s, B_s) \\ & \quad - \lim_{\varepsilon \downarrow 0} \int_{\mathbb{R}^d} (f(s+t, B_s+x) p_t(0, x) - f(\varepsilon+s, B_s+x) p_\varepsilon(0, x)) dx \\ &= -f(s, B_s) + \lim_{\varepsilon \downarrow 0} \int_{\mathbb{R}^d} f(\varepsilon+s, B_s+x) p_\varepsilon(0, x) dx \\ &= -f(s, B_s) + \lim_{\varepsilon \downarrow 0} \mathbb{E}[f(s+\varepsilon, B_{s+\varepsilon}) | \mathcal{F}_s^+] \\ &= -f(s, B_s) + f(s, B_s) \tag{DCT} \\ &= 0. \end{aligned}$$

□

Transience and recurrence

If $B_0 = x$, then $(B_t - x)_{t \geq 0}$ is a standard Brownian motion under \mathbb{P}_x .

Theorem. *Let B be a Brownian motion in \mathbb{R}^d .*

1. *If $d = 1$ then B is point-recurrent, i.e for all x, z , $\{t \geq 0 : B_t = x\}$ is unbounded \mathbb{P}_z -almost-surely.*
2. *If $d = 2$, then B is neighbourhood-recurrent, i.e for all $\varepsilon > 0$ and all x, z , the set of times $\{t \geq 0 : |B_t - z| \leq \varepsilon\}$ is unbounded \mathbb{P}_x -almost-surely. But it does not hit points, i.e $\mathbb{P}_x(\exists t > 0 : B_t = z) = 0$.*
3. *If $d \geq 3$, B is transient, i.e $|B_t| \rightarrow \infty$ as $t \rightarrow \infty$ \mathbb{P}_x -almost-surely.*

Proof.

1. Immediate since $\limsup_{t \rightarrow \infty} B_t = \infty$ and $\liminf_{t \rightarrow \infty} B_t = -\infty$.
2. It suffices to consider the case $z = 0$. Let $\varepsilon < |x| < R$. For $r > 0$ define $T_r = \inf\{t \geq 0 : |B_t| = r\}$, we want $\mathbb{P}_x(T_\varepsilon < T_R)$. Let $H = T_\varepsilon \wedge T_R$ so $H < \infty$ as Brownian motion is unbounded. Let $\varphi(y) = \log |y|$ for $\varepsilon \leq |y| \leq R$ and $\varphi \in \mathcal{C}_b^2(\mathbb{R}^2)$. Then $\Delta \varphi = 0$ in the annulus. So $M_t = \varphi(B_t) - \varphi(B_0) - \int_0^t \frac{1}{2} \Delta \varphi(B_s) ds$ is a \mathcal{F}_t^+ -martingale. Then $M_{t \wedge H} = \varphi(B_{t \wedge H}) - \varphi(B_0)$. Applying the optional stopping theorem gives

$$\begin{aligned} \mathbb{E}_x[\log |B_{t \wedge H}|] &= \log |x| \\ &\rightarrow \mathbb{E}_x[\log |B_H|] = (\log \varepsilon) \mathbb{P}_x(T_\varepsilon < T_R) + (\log R) \mathbb{P}_x(T_R < T_\varepsilon). \end{aligned}$$

Hence

$$\mathbb{P}_x(T_\varepsilon < T_R) = \frac{\log R - \log |x|}{\log R - \log \varepsilon}. \quad (*)$$

Letting $R \rightarrow \infty$, $T_R \rightarrow \infty$ almost-surely so $\mathbb{P}_x(T_\varepsilon < \infty) = 1$. Then

$$\begin{aligned} & \mathbb{P}_x(|B_t| \leq \varepsilon \text{ for some } t > n) \\ &= \mathbb{P}_x(|B_{t+n} - B_n + B_n| \leq \varepsilon \text{ for some } t > 0) \\ &= \int_{\mathbb{R}^2} \underbrace{\mathbb{P}_0(|B_t + y| \leq \varepsilon \text{ for some } t > 0)}_{=1} p_n(x, y) dy \\ &= 1. \end{aligned}$$

Thus $\{t \geq 0 : |B_t| \leq \varepsilon\}$ is unbounded \mathbb{P}_x -almost-surely. Taking $\varepsilon \rightarrow 0$ in $(*)$ shows $\mathbb{P}_x(\text{hit } 0 \text{ before } R) = 0$. Let $R \rightarrow \infty$ so $\mathbb{P}_x(\exists t > 0 : B_t = 0) = 0$ for all $x \neq 0$.

It remains to show $\mathbb{P}_0(B_t = 0 \text{ for some } t > 0) = 0$. Let $a > 0$, so

$$\begin{aligned} \mathbb{P}_0(B_t = 0 \text{ for some } t > a) &= \mathbb{P}_0(B_{t+a} = 0 \text{ for some } t > 0) \\ &= \mathbb{P}_0(B_{t+a} - B_a + B_a = 0 \text{ for some } t > 0) \\ &= \int_{\mathbb{R}^2} \mathbb{P}_0(B_{t+a} - B_a + y = 0 \text{ for some } t > 0) p_a(y) dy \\ &= \int_{\mathbb{R}^2} \mathbb{P}_y(B_t = 0 \text{ for some } t > 0) p_a(y) dy \\ &= 0. \end{aligned}$$

So taking the limit as $a \downarrow 0$ we get $\mathbb{P}_0(B_t = 0 \text{ for some } t > 0) = 0$.

3. Consider first the case $d = 3$ and let $T_r = \inf\{t \geq 0 : |B_t| = r\}$, $\varepsilon \leq |x| \leq R$. Take $H = T_\varepsilon \wedge T_R$, $B_0 = x$. By unboundedness of Brownian motion, $H < \infty$ almost-surely. Let $f(y) = \frac{1}{|y|}$ for $\varepsilon \leq |y| \leq R$ such that $f \in \mathcal{C}_b^2(\mathbb{R}^3)$. Then $\Delta f = 0$ in $\varepsilon \leq |y| \leq R$, so $f(B_t) - f(B_0)$ is a martingale up to H .

The optional stopping theorem gives

$$\mathbb{P}_x(T_\varepsilon < T_R) = \frac{\frac{1}{|x|} - \frac{1}{R}}{\frac{1}{\varepsilon} - \frac{1}{R}}.$$

Sending $R \rightarrow \infty$, we have $T_R \rightarrow \infty$ almost-surely. Hence $\mathbb{P}_x(T_\varepsilon < \infty) = \frac{\varepsilon}{|x|}$. To show $|B_t| \rightarrow \infty$ as $t \rightarrow \infty$, let $A_n = \{|B_t| > n \text{ for all } t \geq T_{n^3}\}$.

Suffices to prove that almost-surely A_n happens eventually. We have

$$\begin{aligned}\mathbb{P}_0(A_n^c) &= \mathbb{P}_0(|B_t| \leq n \text{ for some } t \geq T_{n^3}) \\ &= \mathbb{E}_0 \left[\mathbb{P}_{B_{T_{n^3}}}(|B_t| \leq n \text{ for some } t \geq 0) \right] \\ &\quad \text{(Strong Markov at } T_{n^3} < \infty) \\ &= \mathbb{E}_0 \left[\frac{n}{n^3} \right] \\ &= \frac{1}{n^2}\end{aligned}$$

implying $\sum_{n \geq 1} \mathbb{P}_0(A_n^c) < \infty$ and A_n happens eventually almost-surely.

□

Dirichlet problem

Definition. $D \subseteq \mathbb{R}^d$ is called a *domain* if it is open, non-empty and connected. We say that D satisfies the Poincaré cone condition at $x \in \partial D$ if there exists a non-empty open cone C with origin at x and $r > 0$ such that $C \cap B(x, r) \subseteq D^c$.

Proposition (Dirichlet problem). Let D be a bounded domain in \mathbb{R}^d such that every boundary point of D satisfies the Poincaré cone condition. Let φ be continuous over ∂D and let B be a Brownian motion, $\tau_{\partial D} = \inf\{t \geq 0 : B_t \in \partial D\}$. Then the function

$$u(x) = \mathbb{E}_x[\varphi(B_{\tau_{\partial D}})], \quad x \in \overline{D}$$

is the unique continuous function satisfying $\Delta u = 0$ on D and $u = \varphi$ on ∂D .

We will need some preliminary results before we can prove this.

Theorem. Let $D \subseteq \mathbb{R}^d$ be a domain and $u : D \rightarrow \mathbb{R}$ be measurable and locally bounded. The following are equivalent

- (i) u is twice continuously differentiable and $\Delta u = 0$;
- (ii) For all $B(x, r) \subseteq D$, $u(x) = \frac{1}{|B(x, r)|} \int_{B(x, r)} u(y) dy$;
- (iii) For all $B(x, r) \subseteq D$, $u(x) = \frac{1}{\sigma_{x, r}(\partial B(x, r))} \int_{\partial B(x, r)} u(y) d\sigma_{x, r}(y)$ where $\sigma_{x, r}$ is the surface area measure of $\partial B(x, r)$.

Definition. If u satisfies any of the above, we call u *harmonic* in ∂D .

Proposition (Maximum principle). Let $u : \mathbb{R}^d \rightarrow \mathbb{R}$ be harmonic on D . Then

- (i) If u attains its maximum in D , u is constant in D ;
- (ii) If u is continuous in \overline{D} and D is bounded, then $\max_{x \in \overline{D}} u(x) = \max_{x \in \partial D} u(x)$.

Proof.

- (i) Let M be the maximum. Let $V = \{x \in D : u(x) = M\}$. Then $V \neq \emptyset$ and is relatively closed in D by continuity of u . Let $x \in V$ so there exists $r > 0$ such that $B(x, r) \subseteq D$. Then

$$M = u(x) = \frac{1}{|B(x, r)|} \int_{B(x, r)} u(y) dy \leq M$$

implying $u(y) = M$ for almost all $y \in B(x, r)$. By continuity of u this means $u(y) = M$ for all $y \in B(x, r)$. Hence V is open. Therefore V is a non-empty open set which is closed in D , implying $V = D$ by connectedness of D .

- (ii) Since u is continuous in \overline{D} and D is bounded, u attains its maximum in \overline{D} . By (i), $\max_{\overline{D}} u = \max_{\partial D} u$.

□

Corollary. *If $u_1, u_2 : \mathbb{R}^d \rightarrow \mathbb{R}$ are harmonic in D , D is bounded and u_1, u_2 agree on ∂D then $u_1 = u_2$ in D .*

Proof. $\max_{\overline{D}}(u_1 - u_2) = \max_{\partial D}(u_1 - u_2) = 0$, so $u_1(x) \leq u_2(x)$ for all x . Similarly $u_2(x) \leq u_1(x)$ for all x . □
